Utah Copper's two year record *with*

Utah Copper Company's Plant at Arthur, Utah, where Mitchell Electric Vibrating Screens are in operation. This mill treats 18,000 tons of ore a day.

MITCHELL ELECTRIC VIBRATING SCREEN

The Utah Copper Company was the first great concern to install Mitchell Electric Vibrating Screens. They have been in operation in the company's big mill, at Arthur, Utah, for two years, with astonishing records of efficiency.

COARSE CRUSHING

In coarse crushing work each Mitchell Screen is delivering a screened product of more than 1,200 tons per 24 hours of minus $\frac{1}{2}$ inch material.

FINE CRUSHING, DRY WORK

In fine crushing, dry work, each Mitchell is delivering a screened product of more than 600 tons per 24 hours of minus 10 mesh material.

FINE CRUSHING, WET WORK

In fine crushing, wet work, each Mitchell is delivering a screened product of more than 650 tons per 24 hours of minus 10 mesh material.

The Mitchell forces the meshes up into the material 3,600 times a minute with an impact of from 500 to 1,000 pounds. Therein lies the revolutionary characteristic of the Mitchell—the feature which is making possible the records shown not only at the Utah Copper Company's mill but in a variety of other industries, such as coal and coke, sand and gravel, fertilizer, salt, etc.

Ask us for records of special tests of the Mitchell, which we shall be glad to furnish you together with complete information as to construction and operation

ARE YOU CUTTING CYANIDE COSTS?

The Aero Brand process of making **Cyanide From Air** has done more to reduce cyanide costs in the past three years than all other factors.

The savings made by consumers in Mexico, Canada and the United States already totals hundreds of thousands of dollars.

Notwithstanding high costs of labor and raw materials, Aero Brand Cyanide has always sold basis 100% NaCN, at practically the lowest pre-war prices of sodium cyanide.

The efficiency of Aero Brand Cyanide, basis 100% NaCN, is equal to any other grade. In every instance where it has been given a mill-scale trial it has been adopted as the most economical cyanide to use, on basis of recovered values.

*Send for Booklet A, giving full information
concerning this money-saving product.*

AMERICAN CYANAMID COMPANY

511 Fifth Avenue, New York

MINE SHAFT DANGERS

are reduced with

H. & B. STANDARD CAGES AND SKIPS

"The Line for the Mine"

Superior in design and construction, fully adapted to actual mining conditions, they are the result of long experience in Cage and Skip building.

★ ★ ★

Frames of structural steel shapes give greater stiffness and rigidity, with a saving in weight.

★ ★ ★

An improved form of Safety Dogs provide ample security against accident if the cable fails.

★ ★ ★

Another protection is the Safety Doors required by law in some states. These additional guards against mishap and Automatic Landing Chairs can be furnished.

★ ★ ★

Built to order only, in any size to suit shaft dimensions.

★ ★ ★

We invite correspondence and will be glad to submit complete drawings of any style.

★ ★ ★

The H. & B. BULLETIN will come to you every month if you mention it.

If Better screen cloth were possible Ludlow-Saylor would wear it.

Screens that last!

Modern milling methods require screens of long life and service. The wires *must stay put*—and stand up under hard usage. Uniformity of product and quick discharge are essential even to the last shred of screen.

"Perfect" WIRE CLOTH double crimped

is the perfect screen in every sense of the word. It is uniform, stays rigid and out-wears all other types. Its flat surface and compact structure enables the fine material to be discharged rapidly and completely.

"It's the Double Crimp that counts"

The warp and shoot wires curve gradually over and under each other. The wires are crimped *not bent*. The result is a screen—structurally correct.

The full strength of each wire is retained and long life of useful service is assured.

Send for catalog containing valuable screening data. It is yours for the asking.

-Correct Design

-Careful Construction

- Complete Protection

Three Essentials

The same engineering sagacity must be applied to the question 'of **Paint Protection** as to the design and construction of mine and mill buildings and equipment.

Time and the elements will destroy what has been erected unless all surfaces are protected with a **lasting and durable coating**.

DIXON'S Silica-Graphite Paint protects against dampness, heat, acids and alkalis, liquids and solids. It stays "put" and is good for years of service. Easy to apply and flows smoothly from the brush.

The pigment in DIXON'S Silica-Graphite Paint is a flake formation, Nature's combination of Silica and Graphite. In spreading the flakes form a tough, scale-like covering of great flexibility which prevents cracking.

Write for Booklet 141-B which gives full data.

Joseph Dixon Crucible Company

Jersey City, N. J., U. S. A.

ESTABLISHED 1827

Pacific Coast Sales Office: 444 Market St., San Francisco, Cal.

Dodge Rigid Pillow Block

ADAPTED TO EXTRA HEAVY DUTY FACTORY SERVICE

Lined with Best Grade of Babbitt

SELF OILING

SAFE

You fill the reservoir of this pillow block only once in six months; that saves oil, saves labor and eliminates the necessity of men working around the line shaft while it is in motion.

Dodge rigid pillow blocks are built in capillary and ring-oiling type; they are substantial in form and adapted to the severest kind of service; order from your dealer—he has the complete Dodge line in stock.

One of the ways wire-wound wood pipe is transported.

Distribution main laid on trestle —exposed to the heat of summer and frost of winter.

Wire-wound wood pipe is the easiest of all pipe to handle.

Redwood — Douglas fir

WOOD PIPE
CONTINUOUS STAVE—WIRE WOUND—BORED

Dependable Distribution Systems

The factor which counts for most in a distribution system is dependability — it must be dependable under all conditions of service.

The pipe used must withstand extra heavy demands as in the case of a fire.

The pipe used must withstand sudden overloads without bursting.

The pipe used must carry maximum loads continuously without failure.

The pipe used must remain unaffected by electrolysis.

The pipe used must remain free of tuberculation and scale.

The pipe used must ALWAYS CARRY AS MUCH WATER as when originally laid.

The pipe used must supply water at all times without interruption for household, commercial and industrial uses.

The ONLY PIPE that meets all these demands is Western Wire Wound Wood Pipe.

It is made in sizes from 2 inches up to 32 inches inside diameter and for any pressure required up to 175 pounds per square inch—and higher pressures on special order.

The wide range of sizes makes it possible to select just the size of pipe needed for each particular section or district.

By specifying Western Wood Pipe a pipe of smaller than customary diameter can be selected for a given service because this pipe has the greatest carrying capacity and always will have it—the capacity does not decrease as the length of service increases.

Its adaptability and ease of laying permits the rapid completion of a system.

Bends, turns and connections can be made with standard fittings supplied by the wood pipe manufacturers.

The advice and assistance of our expert engineers, widely experienced in the planning and building of efficient, dependable distribution systems at lowest consistent costs, are at your command.

Let us tell you why Western Wood Pipe is the best pipe obtainable for the distribution system you may have in mind. Address us by wire or mail.

PLYMOUTH

Gasoline Locomotives

Moves 400 Tons of Coal Daily

C. M. Wolf, superintendent of the Morrell Coal Company writes: "Skilled labor is unnecessary to operate your Plymouth Gasoline Locomotive. It picks up a heavier load more quickly and easily than any other system I have found. We pull a heavier load than is understood to be possible, due to the Plymouth's full power at slow speed."

In coal, iron or zinc mines, or wherever earth or mineral demand big haulage, the Plymouth is complete master, with increased tonnage at lower cost and fewer men. Whether underground or on the surface, it multiplies production and profit.

Write for special bulletin on Plymouth service in mines.

AMERICA'S BEST
LUNKENHEIMER
—QUALITY—
SINCE 1862

LUNKENHEIMER REGRINDING VALVES

have firmly established their unparalleled merit by the successful results they have given through many years of satisfactory service.

The metal to metal seat—ground to a tight fit, forms the ideal seating surface to resist the wearing action of steam at high velocity. And the fact that the seating surfaces can be reground (and inexpensive operation easily accomplished) makes the renewal of parts wholly unnecessary.

Their extreme durability due to correctly proportioned parts, high quality materials and expert workmanship insures economy in maintenance.

Globe, Angle and Cross Valves with Inside Screw and with Outside Screw and Yoke; and Horizontal, Angle, Vertical and Swing Check Valves for 200 and 300 pounds working steam pressure.

Specify **Lunkenheimer** and insist on their installation. Distributors of Lunkenheimer Products situated in every commercial centre.

"The Waugh Way Wins"

A Perfect Tribute

THE Tonopah Extension Mining Company, speaking through its Master Mechanic, Mr. H. A. Reid, says of the Waugh Model 8 Drill Sharpener:

"AS we have been using one of your Waugh D. S. 8 drill sharpeners at the Tonopah Extension in Tonopah, and one at the White Caps mine in Manhattan, for a period of over three years with most gratifying results, I wish to state that we consider it the best sharpener on the market today.

"WE have used several different types of machines, changing makes to keep abreast of improvements as they came up. * * * * *

"TO date we have purchased no repairs for any of the equipment, and we consider the Waugh D. S. 8 to be the best machine we have ever used from every standpoint, as to low upkeep, durability, low air consumption, and efficiency."

TRIBUTES of this sort not only point the way to contentment and efficiency in the mine blacksmith shop, but afford further proof of the well-known fact that

Westinghouse

Agitator Motors

Unexcelled in Economy of Operation and Endurance Qualities

When a motor has been designed by Westinghouse Engineers for a special operation and those same engineers select the materials from the large Westinghouse storerooms, this motor, judging from all earlier records, will prove to be the finest motor available for the operation for which it is designed.

The Westinghouse Agitator Motor is an example of the ability of Westinghouse Engineers to design a motor fitted in every detail for the

operation it is to perform. This special type of motor is sturdy, extra heavy, and will resist vibration. The bearings have a special oiling system and the shaft and guide bearings are proportioned to withstand the thrusts that are apt to be encountered. The lower bearing sleeve is of non-corroding alloy.

The thousands of these motors in successful operation today stand as justification of our claims.

Two of
The Victor American Fuel Co.'s
HOISTS
Referred to below

Read What Our Customers Say:

Denver, Colorado, March 18, 1919.

The Denver Engineering Works Co.,
Denver, Colorado.

Dear Sirs:

On March 24, 1913, we purchased two of your electric mine hoists, one having a single drum with a capacity of 14,000 pounds and the other a double drum with a capacity of 12,000 pounds rope pull.

Tests made on the single drum machine show that we are developing 18,600 pounds rope pull on the peak of the load, which is equivalent to an overload of 23%.

Both of these machines have been in continuous operation for six years and our records show that it has never been necessary to make any repairs on either hoist.

Yours truly,
THE VICTOR AMERICAN FUEL CO.

A complete air power unit for mines and prospects

AT MINES where fuel oil is easily procurable, the Chicago Pneumatic Oil Driven Air Compressor is replacing less efficient air power units.

This machine supplies a complete air compressing plant in one unit. The power and air cylinders are direct connected. There are no bothersome chains or belts. The unit operates dependably and economically on low-cost fuel oils. Simplicity

and automatic operation are other advantages contributing to high operating efficiency.

These units are readily adaptable in batteries to large air power requirements. When so installed they eliminate all possibility of complete shut-downs.

Stationary, skid and truck-mounted types are built in several sizes. Ask for bulletin.

NEW YORK ENGINEERING CO.

Above is shown an Empire Gold Dredge under construction in Mambulao Bay, Luzon, P. I. This dredge was designed, built, shipped and erected by the New York Engineering Company. The difficulty of transportation and burning tropical wood was overcome in this case by installing a steam-electric power plant on the dredge; a bad clay condition was successfully combatted by special apparatus and many other special features substantiate the claims of superiority for the Empire Dredge.

A Gold Dredging Problem?

Put it up to us!

From the time when dredge recovery of gold and tin from Placer ground was first proved practicable we have specialized in that field and made the solution of its problems our sole aim.

We make a special study of each particular problem, and from our experience design a dredge to meet the condition. That's the reason why no Empire Dredge has ever had to be redesigned—and they are in operation in all parts of the globe.

We have originated many of the improvements in dredge construction which have greatly added to their efficiency; among them were the first steel hull, the first self-contained steam-electrically driven dredge, the first solution of the clay problem, and many others.

Empire Dredges are built in our own plant, ideally situated in the heart of the district producing the special steels used in their construction, and with the most excellent shipping facilities.

Bring the problem direct to us. We'll find the solution and carry the work through from start to finish.

Have you our catalogue?

NEW YORK ENGINEERING CO.

Handle all Mine and Mill Figure-Work Mechanically

The Monroe takes the burden of intricate Mine and Mill figuring just as your crusher takes the load of ore you feed it.

Pad-and-pencil methods of figuring are just as out-of-date and wasteful as crushing ore by hand-and-arm power.

Would you change your gyratory for a gang of men wielding sledges.

DAILY problems, routine figuring, complicated calculations, special reports, records and determinations—"feed" them all to the Monroe Calculating Machine.

The Monroe has the same capacity for "run-of-mine" figuring as the big crusher has for "run-of-mine" ore.

The Monroe *two-way* mechanism is simplicity itself—a turn of the crank forward to add or multiply—backward to divide or subtract.

Since there is no obligation, send for complete details. Fill out and mail the coupon today.

ORE TESTING

Have you ever carefully considered the reasons for the absolute necessity of having your ore properly tested by a reliable firm before deciding upon the design of a treatment plant, and the fundamental rules that must be born in mind and followed out by those entrusted with such important work?

REASONS

It has been said that "No two individuals are exactly alike", and the same is true of ores, therefore it must be a good investment to eliminate chance and decide on the correct treatment for an ore by tests entrusted to competent and experienced engineers, before the mill is designed, rather than to guess at the flow sheet and then have to re-design and re-build the mill after it has gone into operation and found to be unsuited to the ore. It is better to invest a few hundred in test work rather than lose thousands of dollars for lost time, re-building and poor results.

FUNDAMENTAL RULES

Metallurgical Honesty

Be sure the engineers employed by you have established such a reputation that their results can be relied on, so that the anxiety to obtain for their clients a favorable showing may not lead them to over-state the results.

Practical Results

Tests that are obtained in a laboratory or testing plant by methods that could not be duplicated in practice are of no value; the testing engineers must therefore be men of wide and varied practical experience, to be able to judge of such matters, and the reports gotten up in such shape that a clear decision can be arrived at.

Metallurgical Balance

A close check should be obtained when closing up a test report. In a test report the sum of all the several products should check closely to the value in the heads, otherwise an error has been made in the assays or weights of the various products, which if not corrected would vitiate the results, and therefore the conclusions.

Self Explanatory Results

Test results should be submitted in a clear concise form with graphic illustrations as to the method employed to obtain the results. These should be clear to the lay-man as well as the metallurgist.

For sixteen years we have operated one of the best equipped and most widely known ore testing plants, treating ores from all parts of the world. Our increasing business demonstrates the confidence the mining public has in us and the reliance they place in our results.

Synchronous motors and condensers have made America's electric power go further without increasing generating or transmission equipment.

400 h.p.-150 r.p.m. Synchronous Motor-driving Compressor at copper mine

When synchronous motors should be used

WHEN your power factor is low and you need greater generator, transformer or feeder capacity.

When you are paying for power at a rate which is now, or shortly may be, dependent upon the power factor of your load.

When your voltage regulation is poor on account of an existing induction motor load and production falls off in consequence, synchronous motors will raise the average voltage and help keep it constant.

When continuity of operation is imperative and dirty operating condi-

tions make a small motor air gap inadvisable.

The General Electric Company has designed complete lines of synchronous motors covering a wide range of speeds and capacities which are in extensive use throughout many industries driving rolls, compressors, pumps, grinders, crushers, blowers, fans, conveyors and mills. Some of these motors have been in continuous service for a score of years.

Our experts will be pleased to select suitable synchronous motors for your work.

The FEATHER Valve Compels

(REG. U. S. PAT. OFF.)

Dependable Air Service

AIR Compressors and Compressed Air Services have been rendered sure, safe and reliable by Worthington "FEATHER" Valve. This valve has but one moving part, weighs less than one ounce and functions without friction or hammering action. It is a strip of ribbon steel—strong and long lasting—that seats tightly on ground face slotted seats and allows air or gas to pass by bowing against slotted curved guards, the ends remaining in contact on seat at all times.

All Worthington Air Compressors are "FEATHER" Valve equipped, and are built by Worthington, whose service has attained world dimensions through 80 years' building, designing and improving Pumps and Pumping Machinery for all uses and purposes.

POINTS of American Superiority

1

Occupies less floor space than any other filter on the market.

2

Has no wire windings and cloth remains more open and pliable at all times.

3

Can be redressed in less time than any other filter. Individual sectors can be changed in two minutes. A unit of 400 sq. ft. area can be redressed in less than two hours time.

4

Produces a cake approximately 50% thicker than any other vacuum filter operating on ordinary metallurgical slimes at the same vacuum and speed.

5

When used for filtering and washing the cake shows a constant extraction of 98% and more of the original moisture values left in the cake.

One user of an "American" Filter writes:

"We have in operation here suction filters of two other types of the cylindrical pattern, and the work done by your machine and its popularity with the operators compare very well, and in some particulars exceed that of other types. We prefer the machine because of its compactness, the close filtering work done by it, and particularly because of the ease of renewing the filtering medium.

"The machine seems to be standing up remarkably well, and promises to continue to give indefinitely the same satisfactory service which has been secured from it since its first run."

This company has purchased a second "American" for another operation.

Mining men find the "American" just right for their requirements. Write for the catalogue and tell us your specific problem.

65 BROADWAY, NEW YORK

CHICAGO SALT LAKE CITY SAN FRANCISCO LOS ANGELES

Style "C" Main Adjustable Troughing Roller with 10°, 15° and 20° Trough. Style "R" Main Return Roller.

Style "E" Main Flat Carrying Roller. Style "R" Main Return Roller.

Style "A" Main Troughing Roller with 20° Trough for 20" to 24" belts. Style "S" Main Return Roller.

Style "A" Main Troughing Rollers with 15° Trough for 12" to 14" belt, and 15° or 20° Trough for 16" to 18" belt. Style "S" Main Return Roller.

Rollers that *Really* Lengthen the Life of the Belt

THE following suggestions for lessening the wear of conveyor belts are based on over thirty years' experience in installing scientific conveyor systems.

The Style "C" roller illustrated admits of instant adjustment to meet special conditions in any plant. Styles "A" and "E," while not adjustable, are perfectly finished and have the same high conveying qualities as the Style "C" roller.

The Style "C" Main Adjustable troughing roller has the following points of advantage, some of which may be found in other equipment, but no other one roller contains them all.

(1) **MAXIMUM ANGLE OF TROUGH IS 20°**—The troughing pulleys are adjustable to 3 positions: 10°, 15° and 20° horizontal. If the troughing pulleys are put in their lowest position, a belt of much heavier ply may be used than would ordinarily be possible.

Experience shows that the maximum angle at which a belt may be troughed without finally cracking is 20° and it should be troughed only so much as is necessary to keep the material from spilling. This is why adjustability is so desirable.

The slight gain in the carrying capacity of a belt troughed at 35° over one troughed at 20° is obtained at the price of the premature destruction of the belt, and a belt which is troughed excessively also has a decided tendency to run off the rollers.

(2) **EDGES OF THE TROUGHING AND THE FLAT PULLEYS OVERLAP**—The troughing pulleys overlap the edges of the end pulleys on the center roll. The inside edge of the troughing pulley is considerably under the top line of the center roll pulleys, and all possibility of the belt coming into contact with the edges of any of the pulleys is absolutely eliminated.

(3) **SELF-ADJUSTING BEARINGS**—The shaft of the flat roller is suspended in dustproof babbitted swivel bearings. The bearings are not rigidly fixed to their supports, but are suspended in them and are free to adjust themselves to accommodate any warping of the stringers. Hence the possibility of the shaft binding in the bearings and ceasing to revolve is eliminated.

(4) **FLAT ROLL CARRIES THE LOAD**—Maximum support is given to the belt in the center, where the load is carried, by comparatively long central pulley or roll.

(5) **POSITIVE LUBRICATION AT EACH BEARING SURFACE**—Each bearing surface is provided with an individual compression grease cup effecting positive lubrication.

(6) **CORRECT MECHANICAL DETAILS**—Rollers are ample in every respect.

Rims of the troughing pulleys are reinforced, making it impossible for the rim to wear away and leave a sharp edge to cut the belt.

Shafting is 1 3/16 in. in diameter for all sizes.

Pulleys are 6 in. in diameter, with faces lathe-finished absolutely true with bore, making a true running smooth roll that will not wear the surface of the belt.

Grease cups on troughing pulleys are placed well within pulley rim, thus protected from injury. Set screws are all of ample size and easily accessible.

The experience of Superintendents in hundreds of plants points to Leviathan-Anaconda belts, carried by Main Belting Rollers, as the ideal combination for efficient conveying of all classes of material.

We have prepared two interesting booklets on belting—"Transmission Belts," and "Conveyor Belts." We shall be glad to mail either, or both, on request.

MAIN BELTING COMPANY - Philadelphia

New York Chicago Pittsburgh Atlanta San Francisco

6000 tons in 8 hours

Hoisting four tons per trip from a depth of 275 feet, this Nordberg Hoist at American Coal Mining Co., Bicknell, Indiana, raises 600 tons of coal in eight hours. The hoist is direct connected to an 800 H.P. motor which operates in conjunction with a motor-generator set.

As the mine buys its current from a public utility company, it was not desirable to run the motor-generator set except during the coal hoisting period. At other times a 300 H.P. induction motor is connected to the hoist

through reduction gears, thus enabling the hoist to be operated at slow speed for handling men and materials. A jaw coupling permits disengagement of the small motor when the large one is being used. This is the first time this arrangement has been used on a mine hoist.

Nordberg engineers have solved many usual hoisting problems in both the coal and metal mining fields. Their wide experience makes their advice extremely valuable. Consultation with them may be arranged by appointment; just write.

UNION CONSTRUCTION COMPANY

Section through Neill Jig as set in a sluice-way. The paddle shown in the middle of its swing—dotted lines show its swing-limit $3\frac{1}{2}$ inches total. If the jig is shut down for any reason, the action of the sluice is not interfered with—the jig bed fills and merely forms a larger riffle.

The Great Efficiency of the Neill Jig

in the recovery of fine values, otherwise lost, is due to the fact that it has **twice as much screen area** per square foot of floor space as the plunger type of jig.

There's nothing complicated about the Neill Jig—nothing to get out of order. The pulsion caused by the oscillating paddle causes an alternate upward and downward flow of water through the screen-floor of the jig and the fines which have settled upon it. A layer of shot covering the screen acts as a self-cleaner and permits the passage of fine values but not other coarse material.

Remarkable results have been obtained by the use of Neill Jigs in connection with dredging operations. It absolutely takes care of the fine values so often lost in the sluices—and pays for itself in the savings it makes.

Write for information and descriptive literature

Angle Compound Compressors and Vibrations

In a vertical compressor vibration of the moving parts shakes the machine up and down.

In a horizontal compressor, this vibration shakes it back and forth.

In a cross compound compressor, the connecting rods and crank-shaft form a couple which causes still other vibrations.

In these older types, heavy construction and massive bed plates or foundations are necessary to absorb the vibrations. But these exist, and cause wear and strain on the moving machine.

The perfect balance of the vertical and horizontal moving parts of the **Sullivan Angle Compound Compressor**, assisted by a slight counter weight, practically neutralizes the up and down and back and forth vibration. There is no twisting strain, because the two connecting rod boxes seat cheek to cheek on the crank shaft.

Sullivan Angle Compound
Air Compressor

This balance, smooth running and practical freedom from vibration are responsible for Angle Compound superiority as shown by:

- Smaller foundations and floor space
- Reduction in horse power per unit of air compressed
- Reduction in wear and breakage
- Smaller and lighter units can operate safely at greater speeds, thus reducing initial cost

Other Angle Compound Advantages:

- Accessibility
- Flexible driving arrangements
- "Finger" plate valves
- Removable Cylinder liner
- Aluminum Intercooler tubes
- Inlet unloader with high pressure relief valves
- Capacity single units 400-1300 feet
- Twin units 900-2700 feet

MADE EXCLUSIVELY BY THE

REDWOOD MANUFACTURERS CO.,

1611 Hobart Building, San Francisco

From Prospector to General Manager

We meet the needs of Mining Men

WHATEVER the activities of the mining man, he rightly insists upon dependable equipment and tested materials with which best to do his work. Starting with the prospector, we attend each step of the individual engaged in mining and metallurgy, promoting his efficiency by providing for his exact needs.

To render successfully these diverse services demands the inventive skill and manufacturing capacity of a long-established institution like ours. Specialized needs can only be filled by a house that has grown up with mining and metallurgy and produced the utilitarian factors required by the industry.

Whether for the field work of the prospector or the indoor pursuits of assayer and chemist, we furnish what the operation requires. We maintain a glass blowing department in connection with our business and are prepared to make any special apparatus as per sketch or blue print furnished.

To meet instant needs, we carry large stocks at our headquarters and in our warehouses. In our special display rooms you may inspect Brown Pyrometers and Recording Thermometers, Braun specialties for the assayer, laboratory equipment, glassware, c.p. chemicals, etc., for the assay office. We are inventors and manufacturers of

Class "PRE" Compressors are found in all industries where large direct connected compressors are desired.

1. Cleveland Cliffs Iron Co., Cliffs Shaft Mine, Ishpeming, Mich.
2. Sun Shipbuilding Co., Chester, Pa.
3. In a Pennsylvania Foundry.
4. Erie Forge, Erie, Pa.
5. Presbrey & Copyendale, Barre, Vt.
6. In a large railroad shop in Pennsylvania.

Ingersoll

Ingersoll-Rand Preference

Users of Ingersoll-Rand Compressors know these units to be extraordinary in their simplicity of operation, overall economy and sturdy construction. Their power bills show a less cost per cubic foot of air delivered, while their repair part record is convincing evidence of low upkeep cost.

These are only a few of the reasons for Ingersoll-Rand popularity witnessed by countless installations in all parts of the world—they possibly explain the number of repeat orders and duplicate installations.

Ingersoll-Rand Compressors are built for steam, direct connected, electric or belted drive.

The Class "PRE"-2 Compressors shown in the illustration is fitted with Ingersoll-Rand Plate Valves, has automatic lubrication and is regulated by 5-stage Clearance Control. The motor is direct connected to the shaft of the compressor.

A study of these machines will give you the reasons for Ingersoll-Rand preference.

Let us send you a copy of Bulletin 3126.

Pacific Products *in the Field*

A Pacific Redwood Pipe Line Carries Water to the City of Oroville, California

The illustration shows part of a 20-inch Pacific Machine-banded Redwood pipe-line which was laid in 1911. It supplies water for the city of Oroville and has given uninterrupted service since its installation.

Pacific Redwood pipe is unequalled for carrying water, acid or alkaline solutions. Its long life, satisfactory service and adaptability to extremes of climate have made it the standard wood pipe for mining use.

T. A. RICKARD, - - - Editor

SECRETARY PAYNE, of the Interior Department, has announced that plans are afoot for the greater development of Alaskan resources "through policies that will attract new capital and improve transportation connections with the United States". It is proposed to consolidate the two American shipping lines now serving Alaskan ports and likewise to consolidate the Federal supervision of Alaskan affairs, both proposals being expected to conduce to economy and efficiency.

PREPARATIONS are complete to start removing 20 million tons of worthless overburden that will permit the mining of 5 million tons of rich copper ore in the mine of the United Verde Copper Company at Jerome. The work will be done by steam-shovel, this plan being resorted to after repeated attempts to remove the burning sulphides in the 'fire-stopes' by other methods. Fire first started in the sulphide ore in 1894 and has been burning in certain parts of the mine ever since in spite of efforts to extinguish it by means of steam, water, and carbon dioxide. The project includes the building of a new town adjoining the present site of Jerome, on the 'made' ground that will result from filling the gulch below with waste-rock excavated from the mountainside.

TIN MINING in Cornwall is facing a crisis. Two of the largest companies, Grenville and Dolcoath, are reported to have given provisional notice to 1000 of their employees that operations will be suspended immediately unless definite promise of assistance from the Government be forthcoming, or until the market and operating conditions alter materially. At the present quotation, which is around £270 per ton, the mines are losing money. The operators take the attitude that government regulation during the War reduced by some £500,000 the profits that would have accrued in an open market, and on this contention the plea for a government subsidy is based. Cornwall was the training-school for many of the miners who helped develop the industry in our own country and Dolcoath is one of the most remarkable of the old mines. From its upper levels it produced £1,250,000 in copper ore prior to 1787. The copper was then exhausted, but on sinking deeper tin ore was developed, from which £3,572,179 was realized. At a depth of 3000 feet the tin content of the ore became too low for profitable mining, but lateral work has opened other veins the exploitation of which is expected to produce dividends if

the price of tin is maintained consistently in the neighborhood of £325.

BELATED discovery of previously unsuspected wealth has more than once brought admirers, flatterers, and ready favor where none had been before. Even in Nevada where the people pride themselves on measuring a man's worth by what he is, not what he has, this trait of human frailty is being displayed. There is, it seems, a stray wedge of land in the north-east section of Township 13 N., Range 34 E., Mt. Diablo Base and Meridian, a forlorn outcast that until lately had never been given more than a passing thought by anyone. Recently three counties, Churchill, Mineral, and Nye, suddenly developed an affectionate regard for the erstwhile friendless vagabond, and now are competing with each other to establish the closest kinship. Moreover each county brazenly concedes that its earnest solicitude is occasioned simply and solely by recent developments in the mine of the Broken Hills Silver Corporation whose property happens to be situated in the disputed area. Within a short time high-grade silver ore has netted \$60,000, and \$100,000 worth of ore is said to be blocked out in workings only 150 feet deep. In view of the taxes which will accrue to the county that wins, if the mine develops into the bonanza it promises, it is easy to sense the deeply sympathetic attitude of the contending counties.

MR. JAMES MacNAUGHTON, general manager for the Calumet & Hecla company, is quoted as saying, in effect, that if it were certain that conditions in the copper industry of Michigan would continue as they are today most of the mines in the district would suspend operations immediately. Ahmeek, Isle Royale, and some of the conglomerate-lode enterprises are exceptions to the general rule; they are returning a small profit. But there is little immediate comfort in the situation except the fact that the physical condition of the mines is not essentially changed. There is plenty of 'rock' of a grade that has been profitably treated in years past, and there is a prevailing optimism that sees a readjustment not far in the future that will enable the mines again to be operated on a profitable basis. Some of the factors that have helped put the Michigan companies in this unfavorable position are shared equally by all of the copper producers, but in some respects they have fared worse than their friends in the Western States. The proximity of

the automobile-manufacturing districts with their highly-paid jobs has made it possible for the miner to get lucrative and agreeable employment with little difficulty. These high wages have attracted the best miners and have made it difficult to maintain a reasonable degree of individual efficiency among the men who remained at the mines. Another handicap which is being felt more than ever is the dependence in a large measure upon steam for prime motive power, and the unusual amount of hoisting and hauling of large quantities of low-grade material. The copper companies burn annually more than a million tons of coal, so that an increase of \$5 in the price per ton at once adds \$5,000,000 to the operating costs. The stock of Calumet & Hecla, that has often sold for \$1000 and has paid its holders 152 millions in dividends, is now quoted at \$320 per share, the lowest level reached in 40 years. A dividend of \$5 recently posted came out of surplus, while the Quincy company, always reputed as being one of the reliable dividend payers, has just found it advisable to pass its regular payment. Nevertheless Quincy is completing the erection of the largest hoisting engine in existence. It weighs, complete, 900 tons and it is designed to hoist ore from a sloping depth of 12,500 feet. The other companies are going ahead too; they have confidence in the future. They feel sure that the price of copper will go up and that the cost of production will come down; that it will be possible again to make a profit from ore that contains only a little more than one per cent copper.

DISCUSSION on the status of silver has almost pushed the gold problem to one side, for the moment. We take pleasure in publishing a letter from Mr. Charles Butters, who needs no introduction. It will be noted that Mr. Butters was uncertain whether his letter ought to be published; that adds to the interest of it, for communications that are so frank as to verge upon indiscretion are just the ones most of us like to read. Mr. Butters, of course, writes as the owner of silver mines in Mexico; his study of the subject is prompted by enlightened self-interest, to which none can take objection. He makes a plea for the greater use of silver, insisting that the countries of Europe have almost abandoned the use of the metal, and hope that we shall be driven to do likewise. Among the Mexicans there is a great and insistent demand for silver coins, and we can fill that demand to our advantage, and theirs, if we awaken to the opportunity. American silver coins are welcome in South America also, and in the Orient, for the world is nearly bare of white money. Mr. Butters proposes to pay his current obligations, to tradesmen and others, in silver; he would like the silver-mining companies to pay their dividends in units of their own metallic product. It is a pious idea, but we anticipate that those receiving silver dollars would deposit them in the bank, preferring to use checks or Federal Reserve bank-notes. Something may be done with the peoples among whom the credit system has been undeveloped, but those used to the exchange of notes do not care to

fill their pockets or their safes with the heavy discs of the Mint. Indeed in a perfect world all settlements would be made by exchange of I. O. U.s; it is only in a world rendered imperfect by folly, hysteria, and dishonesty that a hard basis of metal is requisite. At this time when the folly, hysteria, and dishonesty of mankind, as individuals and as nations, are particularly in evidence we find the need for something safer than a signed paper, and that is why we are so anxious to enlarge our metallic base, which is the shock-absorber of our commerce.

THE Exploration Company, which acts as the agent, in London, of the Treadwell group of mining companies, has issued a circular summarizing the position of these companies at the end of the financial year. The information is taken directly from the reports of Mr. F. W. Bradley, who is president of the three companies operating on Douglas island, Alaska. The premier enterprise, the Alaska Treadwell, made a profit of \$17,500 from commercial business and interest on investments. A surplus of nearly \$2,000,000 of assets over liabilities, exclusive of property and plant, places the company in a strong position to carry out its policy of acquiring new mines in Alaska, thereby establishing the continuity of the enterprise. The Alaska United shows a deficit of \$78,900, the operation of the Ready Bullion mine, which is the only one not drowned by the caving at the surface, having been rendered unprofitable by the excessive cost. Mr. Bradley suggests that two courses are open, either to suspend work "until after the purchasing power of gold becomes greater", or to gouge the mine as quickly as possible. He recommends, and the directors have approved, the second plan of action. The Alaska Mexican, which is flooded, made a loss of \$21,250. It has realizable assets worth \$177,900. Working options on three gold and silver properties in Alaska have been secured, and examinations are being made. It is sad to contemplate the condition of this famous group of mines, and it is much to be hoped that their good tradition will be perpetuated by the transfer of their remaining capital to some new and promising venture in Alaska.

'CHLORIDE VOLATILIZATION' has been successfully applied in the treatment of low-grade copper ore by the Pope-Shenon Mining Co. at its property near Salmon, Idaho. Two comparatively simple operations are involved in the treatment by which the metal in the oxidized ore is recovered in the form of high-grade bullion. The process, developed by Dr. Robert H. Bradford, consulting metallurgist for the company, is a departure from the ordinary methods of smelting. The ground ore, mixed with pulverized calcium chloride in proper proportion, is treated in an oil-fired revolving roaster in which the metal is volatilized and driven off as a fume of copper chloride. The fume is passed through a Cottrell electric treater that functions perfectly in separating the precipitated particles of copper chloride from the gaseous constituents of the smoke. The dust is collected, mixed with lime and charcoal, and fused in a

melting-furnace in which oil is likewise used as the fuel. The molten copper is tapped into bullion-molds as a marketable product, while the slag, which is impure calcium chloride, is crushed and reverted to the original roaster to supply the chloride for subsequent operations. Several features of the process appeal to the metallurgist. The only raw materials required are charcoal and lime, in addition to the necessary fuel-oil. A unit as small as 50 tons is economically practicable; the machinery is not complicated; and the success of neither the roasting nor the fusion depends upon delicate chemical reaction or precise regulation of temperature. Sufficient bullion has been made to demonstrate the success of the process, but the most advantageous mixtures of material and exact degree of roasting for the best results are yet to be determined. The satisfactory performance of the new plant emphasizes the possibilities in combining the operations of modern metallurgy in novel ways and is a credit to the ingenuity and resource of Dr. Bradford.

Americanization

Last week we discussed immigration, and the proposal to restrict, if not to stop entirely, the entry of foreigners. During the decade from 1909 to 1918 inclusive there were admitted into the United States 6,958,034 immigrants, of whom 21% could neither read nor write. In 1910 half of those living in California were foreign-born or the children of the foreign-born. Here admittedly are hard nuts to crack, or, shall we say, tough morsels to digest. Those who oppose the placing of an embargo on immigration as being contrary to the American idea, and as being, in large measure, the shirking of a national responsibility, are compelled to face the duty of making the best of the foreign elements in our population; in short, they advocate systematic Americanization.

Americanization is the making of Americans; that is the bringing of men and women into sympathy with the ideals of the American republic. As those born in this country are Americans in fact, the term Americanization implies the conversion of aliens into American citizens. To do this effectively it is necessary to employ two processes, education and naturalization. The latter process, which is a legal formality, is of no avail in making an alien into a real American citizen unless he has been so educated as to understand and love the traditions and ideas that have made a nation out of the diverse population living in the United States. This nation consists of men and women who themselves or whose progenitors came from foreign countries. They have become united and assimilated by sharing the same experiences; they have fought for their freedom; they have battled among themselves over great principles; they have developed their own ideas of liberty, of law, and of government; they have been fused, by living and working together, by sorrowing and rejoicing together, by thinking and dreaming together, into one nation, separate from any other and unlike any other. This unlikeness is the essence of Americanism, to it the people of the United States owe their identity, upon it they base their ways of living, that is, their civilization. In order

to maintain and develop this civilization, this American way of living, with all that it connotes in the conduct of domestic, civic, and national affairs, it is imperative that the incoming foreigner—the immigrant—shall not remain an outsider, alien to the spirit of the country. As Roosevelt said, this must not be "a polyglot boarding-house"; it must be a home in which all those under the same roof shall understand each other and work together in harmony for the good of all. Therefore the newcomer must be taught the habits and imbued with the aspirations of the American citizen. First of all, he must learn our language, for without that no complete understanding is possible; next, he must acquire some knowledge of the history of the country, so that he may appreciate its past; then he must become reasonably well informed concerning the constitution, laws, and system of government under which he expects to live. The success of this educative process will depend not only upon him, but also upon those who undertake to teach him. There must be mutual sympathy. The foreigner must want to become Americanized and we must make it evident to him that we desire to help him to his graduation as a citizen. In short, Americanization is a sympathetic process whereby the foreigner, ceasing to be an alien, becomes a fellow citizen with the direct inheritors of the American tradition.

The foregoing is, we believe, a fair statement of a subject that is vital to the welfare of this republic. Emphasis must be placed upon the need for sympathetic contact with the alien. This means neighborly intercourse between American men and women on the one side and foreign men and women on the other. The children, if let alone, will follow the instinctive sociability of unsophisticated youth. Colonies of alien people should be disintegrated, not by force, but by kindness, through the establishment of American social settlements intended to win the goodwill and understanding of those about them, by mingling with them unaffectedly and naturally. They will have to overcome the opposition of political bosses, bigots, labor contractors, and hyphenated bankers, all of whom profit from the social detachment of whole groups or even communities of foreigners. To be effective in this work of Americanization the social worker must learn the language of those whom he desires to befriend. Undigested alien communities are a menace to the health of our body politic; they must be assimilated by kindness if we are to escape chronic political dyspepsia. It is a condition that confronts us, not an economic theory. The War and its aftermath have greatly aggravated the harmfulness of the un-Americanized elements in our population, because the War made calls upon the devotion of the Europeans in our midst and those calls were not all in accord with the national purpose as it was finally defined by our own participation in the conflict. Since hostilities were formally stopped by the Armistice we have been plagued by various propaganda in favor of different European peoples, all tending to elicit sympathy with one or another of them, and thereby superimpose some sort of European sentiment on top of American patriotism. A German, an Irish, a British, or any other propa-

ganda that draws the citizen away from his proper allegiance to the United States by developing an un-American point of view on matters of national concern is more than objectionable, it is pestilential. Dislike of it necessitates neither a frothy provincialism nor a sloppy internationalism. All appeals for, or against, any propaganda based upon European sentiment have a disintegrating effect on the national spirit, because they serve to accentuate prejudices that are non-American. If the alien elements in this country are to be Americanized, it must be done by developing sympathy with American ideals and not by making calls upon an allegiance that has been surrendered to the United States. Hearst's campaign, for example, may make people anti-British or pro-British, but it does not help in the least—on the contrary, it hinders—the Americanization not of the British alone, but of the Germans or Irish or any others to whom his propaganda makes any sort of appeal. Most Americans object to the repeated compulsion to align themselves for or against such schemes, which serve merely as an irritant entirely subversive of the sincere effort to cause the diverse European elements to forget their origins in the warmth of their allegiance to the country of their adoption. Americanization assumes the existence of a genuine Americanism, which, while not lacking intelligent sympathy with other countries and desiring friendly intercourse with them, is determined to follow its own ideals and achieve its own destiny.

A Code of Ethics

A special committee of the American Society of Mechanical Engineers has prepared a tentative draft of a 'Code of Ethics', which it is proposed to submit for approval to all of the national engineering organizations, with the hope that, if generally adopted, it may become a universal code recognized by engineers in all branches of the profession. The 14 articles of the proposed code were published in our issue of June 19. To some it may seem futile to attempt to improve upon the familiar set of ten admonitions that were first promulgated on Mt. Sinai, and equally so to attempt to legislate morals into people either by imperial or democratic edict. Yet, if a formal code of ethics we must have, let it be brief and to the point. We venture the opinion that some of the articles proposed by the Mechanical Engineers are of too little importance and that some are either inconsistent or not clearly expressed. If they be deleted or revised the essential parts will gain emphasis, and the value of the entire code will be increased. For example, Article 8 reads: "He should satisfy himself before taking over the work of another consulting engineer that good and sufficient reasons exist for the change". There can be but one "good and sufficient reason" for a change other than the voluntary resignation of the first engineer himself. That reason is the dissatisfaction of the client who is presumably the man that foots the bills. Few mining engineers would care to continue in the capacity of consultant to a company that wanted to get rid of

them, but that was unable to do so because ethics, or etiquette, would prevent another engineer from taking up the work. Why engineer No. 2 should pass judgment on the motives of the employer or client in seeking the services of another consultant is hard to see, either from an ethical, or from any other codic viewpoint. Article 9 declares that "He must base all reports and expert testimony on facts or upon theories founded only on sound engineering principles and experience". In the name of common sense on what else could an intelligent man base his expert opinion? Indeed, we must assume that all engineers have intelligence; and even if some lack it, the mere fact does not make them guilty of any breach of ethics. Certainly we cannot declare 'un-ethical', or heretical, one group of engineers because their conclusions based on the identical set of facts diverge widely from those of another group. Judged by that standard every lawsuit involving expert testimony from engineers would produce material for the consideration of the proposed Standing Committee on Professional Conduct. Article 10 reads: "He must not regard as his own any information which is not common knowledge or public property, but which he obtained confidentially from his client or while engaged as an employee. He is, however, justified in using such data or information in his own private practice as forming part of his professional experience." These two ideas are perhaps not flatly contradictory, but they read as if they were. If they mean anything it is that an engineer should not publish confidential information obtained during the performance of his professional duty without the consent of his client. Next is Article 11, which says "He should do everything within his power to prevent sensational, exaggerated, or unwarranted statements about engineering work being made through the public press. First descriptions of new inventions, processes, etc., for publication should be furnished only to the engineering societies or to the technical press." In view of the proclivity of the "public press", which presumably refers to the daily newspapers, to gather sensational and exaggerated, if not unwarranted, statements, the engineer who fulfilled the letter of this mandate would have little time for his professional work. As to the second injunction, the impress of a spirit kindred to our own is manifest. We appreciate the motive, and are duly grateful; but is there any essential obligation for the engineer to do either of these things in order to be 'ethical'? Would the failure on his part to do either be a reasonable excuse for disciplinary action on the part of the national engineering society to which he happened to belong? We mention these things simply to illustrate the point that there has not been exercised enough care and discrimination in the preparation of what is expected to be an enduring code. The various societies may well formulate a statement of essential principles governing the professional conduct of their members, but they should take time to decide just exactly what those principles should be. The Decalogue was written on stone.

DISCUSSION

Concerning Silver

The Editor:

Sir—On account of the shortage of silver coin in France and Germany and England, travelers going abroad well supplied with silver coins find their way made easy. An American 25c.-piece represents something like two francs, a 10c.-piece would be very welcome money, being about the size of a 50-centime piece. American banking agencies in Paris would find a profitable business in shipping American coinage for their customers. We do thousands of dollars worth of business weekly here at our mines in Mexico with American money. A Mexican silver coin is a great rarity. This has all happened within a couple of years. This change has happened so rapidly that in the State of Sonora all prices are now quoted in American dollars instead of Mexican pesos. They call them "do-lars" and are very fond of them. They look pretty good beside a Carranza bill, 100 to the \$. It would seem good business for the American mints to take any kind of fine-silver bars presented to them and return American silver coins worth per ounce anywhere from \$1.29 to \$1.38 for subsidiary coins and make this coin by taking in bars at \$1 per ounce on any market-price below the coinage-value. Our mints could afford to run 24 hours per day on such business.

The silver producer could surely afford to pay the mint charge, if any, and the express charges, and instead of sending out checks send real newly minted silver coin. People would soon realize that there was such a thing as a silver industry if they saw the real stuff come pouring into the channels of trade, piling up in the safes, like the old days of California. A new interest would be taken in silver mining by the very sight of the bright new money going from hand to hand; a greater tendency to save would be instilled by the sight and ownership of coin as against paper or checks. Many a man would think twice before he counted out and parted with ten thousand new bright silver dollars in ten bags of a thousand each. The bulk appeal of ten bags of bright coin is much greater than that of a cheque with "Ten Thousand Dollars" written upon it.

We talk of interesting people in silver mining by telling how much profit they can make. Profit can be made in rubber, bricks, automobiles, steel, hats, shoes, baking companies, street-car companies, etc., but that is not silver mining. Interest them in the metal itself. How many shareholders in a silver mine paying dividends ever see any of the company's product fresh from the Mint—new bright clean coin? Your own money straight from

your own mines—great business! Does not every automobile dealer get a big window on the principal street and gloat over his bright new shiny car, which, the minute it has been sold and once around the block, \$1000 comes off its value. While our bright new silver may lose its gloss in going from hand to hand, it still holds its value, good stuff to own; get some, put it away in a safe deposit, always handy. Just about \$5 apiece all around would be as much as the great Government storage before the War. That storage is much safer, much more useful, and much more liable to be a source of political safety for the people in time of trouble, in their own pockets than in any great tempting pile represented by floating paper.

How many officers of a silver mining company ever see an ounce of their product? As a rule, none of the home officers, boards of directors, or secretaries. How many of the officers at the mine? Probably one or two—the melter and the local secretary. How many of the miners or mill-hands, or town's-people where the silver is produced? Probably very few. How many silver dollars does the average shareholder of the Nipissing Silver Mines Co., of which there are 14,000 in America and Canada, carry about with him? I will venture to state you could not find 500 single American dollars on the lot. You will find some paper money and subsidiary coin made at a price of about \$1.38 an ounce out of silver for which the Nipissing received about 60 cents an ounce. What is the matter with giving these 14,000 shareholders their two million silver dollars in 14,000 packages marked 'Nipissing Silver'? Why, say, they would never want to spend one of them. It would be the greatest advertisement the silver-mining industry could possibly have, every shareholder receiving from a hundred to three hundred new dollars. Where is your imagination if you cannot see the instantaneous effect of every silver-mining company paying out all its production in dollars, or halves or quarters or dimes if you want them, instead of offering bars like merchandise to people who are doing their best to knock their product. Everyone knows that if you have a \$20 gold-piece and don't change it you have always got \$20. Just change that \$20 gold-piece into 50c.-pieces and 10c.-pieces and walk down the pike with your girl—you will not find it intact after one turn; in fact, you can't for the life of you square your account, try as hard as you can. Now, why do the producers decline to put their product into such small pieces that it scatters itself without effort? It will cost some trouble and about 2% of its value, but there can be no such thing as a point of saturation because you can always buy both supplies and labor with American silver coin and your

shareholders will never send your dividend package back and demand gold; so why don't we adopt this plan? Let someone tell me why. Why? Because bankers and financiers can make more money out of the people's money by handling it for them. They can do as much with a little coin and a lot of paper as the individuals can with all coin. This process has been going on so long and so cleverly that most of the world at the present time sees absolutely no gold and they are getting it down so fine that shortly there will be no use for silver—paper, copper, nickel, and nickel and silver taking the place. This is not good for either the public or the gold or silver producer.

A gold miner is supposed to be doing what I have outlined above, paying out for everything in his own product, but as a matter of fact, while he used to do this, he does it no longer. He is now using paper and his single dollar is stretched to about twenty dollars in paper credit. For this he gets no benefit. If everyone should demand gold payment in actual coin you would soon see the price of paper fall and the gold producer would come into his own. Formerly in California the gold miner did pay in gold coin. It would not suit the banker or financier to see actual silver used and demanded in place of paper, because he could not make two into one. He would have to produce the coin for payments. The silver miner wants silver to circulate as coin everywhere and not see shipplasters and postage-stamps take its place. The producer is the one to start it again. Do you suppose if the copper producer could pay in kind as easily as a silver producer that he would ever try to force his bulk production on a world that can't pay for it in gold? No, he would keep on paying in kind just as the gold miner is actually supposed to be doing. Why, the lead miners, zinc miners, or producers of any kind, would never quit if they could do what the gold miner does. There is only one other who can do that—pay in kind—and that is the silver miner, who paid in kind in a rich and prosperous Mexico for three hundred years, and this was only stopped by absolute destruction of the public mints so that the gold standard could be established in order that bankers could enrich themselves by issuing paper, and finally between the bankers and the public officials the people of Mexico have been absolutely robbed of all their metallic wealth and the credit of Mexico absolutely ruined. I say the metallic money is safest in the hands of the people. No country can be ruined by scheming officials if its people hold the actual coin.

The logical conclusion of such a plan would mean that every convenience should be given to the silver miner for coinage and we should have local mints as they formerly had them in Mexico. For instance, every State producing large amounts of silver, like Montana, Colorado, Nevada, should have a local mint for silver coin only. Imagine Anaconda paying out its total silver production in wages and for supplies, because, as silver is only a by-product, no doubt that these two items would absorb their production of about ten million ounces of silver. Nevada would become an exporter of silver coin; Colorado also. Carry this plan out and the United States

would soon realize that there was a real silver industry and she was a leader in this industry. There is a world of sentiment in this idea of actually seeing, having, owning, and handling masses of silver coin. This sentiment, which could be so easily aroused, is at present absent from this silver question. We deal only in figures and hide our bullion in safes and banks. Silver is such a rarity that even the transfer of a truck-load of bars always attracts crowds. Coin the bars, that's what I say, and distribute instead of hiding them away and hunting a customer for an article we produce but refuse to use ourselves, preferring to let other people carry the silver and we our paper. The West will wake up some day and find the East the real bankers of the world, because they are, and have been, accumulating real money—gold and silver. I hope these notes will not be misunderstood as having connection with the free coinage of silver. All we ask the Mint to do is to convert our bullion at the market-price into silver coin. If they will do this, and it surely would be a profitable business, I should like to know from Mr. Baker how much his present coinage capacity is on a 24-hour basis with fine bars. The refining capacity of the United States is ample. Next, what is the coining capacity? Is there any valid reason that would prevent the Mint from doing this business? If such a reason exists the producers should see, too, that such a reason should be promptly removed. It may be doubtful whether this scheme should be published, as it might arouse powerful enemies, whom such a plan would not suit at all. I am not sure of this, however. You would gain friends as well as enemies.

CHARLES BUTTERS.

Combinations of Gold

The Editor:

Sir—On page 103 of the 'Mining Engineers' Handbook' in the paragraph entitled 'Gold-Bearing Minerals', I find the following statement: "In some of these minerals, when the ores are refractory, it may exist as an involved telluride, or as a bismuth compound (Richard Pearce)."

Having frequently seen in print the statement that tellurium is the only element with which gold is found in chemical combination, the sentence quoted appears to me as unusual. The question is of particular interest to me as our ores carry a percentage of bismuth as well as gold. It appears to be also a subject of some general scientific as well as economic interest.

J. H. MOCKETT JR.

Red Cliff, Colorado, June 14.

[Gold is found in combination with selenium as a selenide, with silver as electrum, with mercury as amalgam, with rhodium as rhodite, with palladium as an undetermined mineral. The combination with bismuth was found in Australia and is called maldonite.—EDITOR.]

REFUGEES ON THE ROAD

A TRAINLOAD OF REVOLTOSOS

The Mexican Revolution

By An Occasional Correspondent

Within two months Carranza has fallen, just when he was least expected to do so. Long ago in 1915, even just after the destruction of Villa's army in the Celaya campaign, everyone was saying "Carranza can't last six months". And even more confident of speedy disaster for the Mexican "scourge of God" were the prophets of 1916 as they saw rapidly pass into history the typhus epidemic, the wholesale repudiation of Carranza money, the Carrizal massacre, and the looting of the State banks of issue. Yet undismayed by these Mexican Cassandras, Carranza proceeds in 1917 to boldly launch a brand new constitution and to exchange his uncertain post of 'First Chief' for the dignified office of national dictator or 'President'.

Carranza was never popular in Central and Southern Mexico, for he had treated this most densely populated part of the country like a conquered province ever since his triumphant entry into Mexico City from the north in August 1914. His general unpopularity in part accounts for his inability to pacify the country and suppress the countless rebel or bandit leaders who under various designations as Zapatistas, Villistas, Felicistas, etc., kept up a constant turmoil in all the rural districts sufficiently fertile to be self-sustaining for their troops. Even to guard the cities and railways, Carranza has had to maintain an army of 150,000 men, the most expensive one in Mexican history, involving in 1917, even, an expenditure nearly thrice what Huerta's army, of a similar size, had cost. As Carranza paid them about the same wages as Huerta, and Mexican soldiers feed themselves, the difference cannot be explained by the extra price for the limited quantity of munitions consumed, but only by graft on a colossal scale.

Carranza's leadership of his party was always analogous to that of a cowboy whose pony has managed to keep in advance of a stampeding herd of cattle, and his attempt to suppress graft well illustrates this. In 1917, as an aftermath of the Mexican-American Peace Confer-

ence, Carranza engaged Henry Bruère of New York to visit Mexico and revise his financial accounting system. One of the principal changes due to Bruère's advice was the organization of a general purchasing agency for the army called Departamento de Establecimientos Fabriles y Aprovechamiento Militar, which was not under the War Ministry but directly under the control of the President himself. Anyone selling merchandise to this new department had to furnish his bill in sextuplicate, so that it had to be approved by six separate officials before a warrant could be issued for payment. When this excellent system had been guaranteed a sincere trial by the naming of a (relatively) honest officer, General Murguia, as head of the department, it really seemed as if the days of wholesale military graft were numbered. And so they would have been, had not Carranza harkened to the pleas of his favorite generals, like Juan Barragan, the "Mexican Adonis" and Chief of Staff, and allowed them to continue to make their own purchases as heretofore.

Thus, in spite of an increase in Federal and local taxation of three to eight times the rates prevalent under Porfirio Diaz, the Carranza regime was always hard up. It had no money to construct new streets or public edifices, or even to repair those already in existence. The minor bureaucracy had usually to accept part of its wages in bonds, while the pay of school-teachers was often in arrears and numerous schools were closed entirely for lack of funds. The few big cities were crowded, but not from normal growth, for their surplus population represented the refugees who had fled from the chronic disorder of their rural homes. All Mexico seemed slipping back into the barbarism of the early nineteenth century. The flow of foreign capital for investment had practically stopped in 1914, for who would risk more money in a country where vast sums previously planted had already been jeopardized, rendered unproductive, and even wiped out completely by brigandage on the one

hand and an unscrupulous anti-foreign government on the other.

Such in brief was the situation last summer when candidacies for the presidency began to be launched. Carranza's term ran until December 31, 1920, and the election to choose his successor was scheduled to take place the preceding July. From the very beginning there were only two noteworthy candidacies, those of Pablo Gonzales and Alvaro Obregon, the two generals of divisions who shared between them the command of the Carranza armies when they marched victoriously south in 1914. Gonzales is reputed to have spent five years as a youth in California, where he married his American wife. Later, he became a commander of *Rurales* (rural police) in Nuevo Leon, but was unknown to fame till he joined Carranza's forlorn hope to fight Huerta, in 1913. As a field-officer he showed some talent for organization but none for strategy, so that he doubtless owed his high command to the personal favoritism of the First Chief. Like most of the Carranza generals, he found revolution a profitable occupation and cleaned up perhaps the biggest fortune of the gang. In 1918 he possessed the huge sum required for planting and harvesting nearly the whole State of Morelos, then just won from the Zapatistas, and his total reward from his patriotic labors is estimated to exceed 5,000,000 pesos.

Younger by several years than his middle-aged rival, Alvaro Obregon hails from a small town in Sonora where he owned a farm and was mayor at the beginning of the revolution in 1910. He then raised a company of volunteers and did some fighting for Madero, but did not attain distinction until Sonora rebelled against Huerta in 1913. It was the Sonoran army that first successfully defied Huerta and saved Carranza when he fled west from his early defeats. Exhibiting marked military talent, Obregon soon rose to the command of the Sonoran army, and in 1914 he marched south along the west coast and captured Guadalajara, while the ever-victorious army of Generals Angeles and Villa was breaking Huerta's power on the central plateau.

When Carranza was cast off as First Chief by the military convention at Aguascalientes, in October 1914, and had to flee for refuge to Vera Cruz, it was Obregon who led his Sonorans to the rescue and reorganized the army during the following winter. In his spring campaign against the Convention army led by Villa, Obregon re-captured Puebla in January, and by May had annihilated his opponents as a result of his victories between Celaya and Leon, where he lost his right army by a shell. Shortly after the transfer of the Carranza government to Mexico City, in September 1915, Obregon became Secretary of the Army and Navy, and held this post till his retirement from politics a year later, after his marriage to a Sonoran lady of large estate.

Until this spring, the presidential campaign proceeded along peaceful lines. Obregon toured the country to greet his partisans, and both he and Gonzales subsidized newspapers in the State capitals as well as in the metropolises. In the latter place, Obregon's friends started last summer 'El Heraldo' and this year 'El Monitor' as

dailies, while Gonzales launched 'El Liberal'; all this in opposition to the old established dailies 'El Universal', 'Excelsior', and 'El Demócrata'. New posters announcing a candidate's merits were struck off every little while and pasted on the billboards of every post-office town in the country.

Carranza meanwhile remained, in his public utterance, quite neutral as between the rivals, and frequently announced his intention to abide by the letter of the law, both by holding the July election and by retirement in December in favor of the successful candidate; but suddenly he changed his attitude and Mexico awoke one morning in March to see blazoned on every billboard the posters announcing the launching of the presidential candidacy of Ygnacio Bonillas, then living at Washington as Mexican ambassador. Bonillas was born nearly 60 years ago in northern Mexico and completed his education for a civil engineer at the Massachusetts Institute of Technology, at Boston. Practising his profession for awhile in our South-West, he removed later to the northwest of Mexico, where he made a good income as an engineer. He joined Carranza's army in 1913 and so far gained the First Chief's favor that on the establishment of the Government at the capital in 1915, he was appointed a cabinet minister in charge of the Department of Communications. Well educated and of fair administrative ability, Bonillas, unlike the majority of his confreres, had kept himself clear of graft. He was as ideal a candidate, from every personal standpoint, as could be found among the Carranzista leaders, and had his backing been of a less sinister character, he might have caught the popular fancy. As it was, everyone began to ponder as to Carranza's motives in proposing Bonillas, and advertising him, regardless of expense, from Guatemala to the Rio Grande. Some said that he was booked for the rôle of the earlier Gonzales, the henchman of Porfirio Diaz, who held the presidential office after Diaz's first term, from 1880 to 1884, and amended the Constitution so that his master could legally get himself re-elected in 1884 and continue as president indefinitely. Others believed him to be a mere stalking-horse for Luis Cabrera, the Secretary of the Treasury and one of the most cunning hypocritical rogues of the Carranza gang; they anticipated that the presidency, once gained by Bonillas' popularity, would shortly be resigned in favor of Don Luis, the most cordially hated man in Mexico but nevertheless the right bower of the Carranza regime.

At the beginning of April, the Bonillas backers became bolder and summoned Obregon from his political campaign in Nuevo Leon to Mexico City, where he was accused of conspiracy in connection with the trial of Cejudo. The latter—a famous Zapatista general for many years in Vera Cruz—was accused of fraud, in that his recent acceptance of amnesty from Carranza had been merely the favorite Zapatista trick for re-stocking the surrendered troops with money and munitions as a preliminary to again becoming rebels. Although the letter incriminating Obregon with the Zapatistas was declared by Cejudo to be a forgery, the former was detained in the capital under surveillance "pending further investi-

gation". Soon eluding his captors, Obregon skipped to Michoacan, and his escape was the signal for the revolt

For several weeks the revolt progressed slowly. Carranza prepared to invade Sonora from Chihuahua and

VENUSTIANO CARRANZA

ALVARO OBREGON

PANCHO VILLA

De la Huerta to capture Sinaloa. The legal governors of Michoacan, Zacatecas, and Guerrero declared for Sonora, as did also a number of rebel leaders; including the Zapatista, General Genevo de la O. of Morelos, the Villista, General Pelaez of Vera Cruz, and the Oaxaqueño, General Mexequiera. In later April, it looked as if the new war might continue indefinitely with Obregon

THE RURALES

holding the whole Pacific Coast region and Carranza the remainder of the country.

In the first week of May luck deserted its erstwhile favorite, Carranza, for General Pablo Gonzales joined the rebels, with most of the army of the East, captured Puebla, and threatened Mexico City. After sending

of Sonora, whose governor, Adolfo De la Huerta, proclaimed the Plan of Agua Prieta as the charter of a new revolution.

General Murguia south with 5000 men to hold Gonzales at bay, Carranza loaded 15 trains with his chief officials and valuables and prepared to repeat his manœuvre of 1914 by retiring his government to Vera Cruz. Yet history refuses to repeat itself on demand, so Carranza never reached Vera Cruz, but was overwhelmed by the enemy near the eastern edge of the central plateau and obliged to flee on horseback into the mountains of Puebla with a few followers. Here the end came suddenly on the night of May 22, when Carranza was shot by an attack on his tent by a body of supposedly friendly troops. Amnesty to leave the country was even then on its way from General Obregon, but it arrived too late to save the fallen dictator.

Meanwhile the triumphant revolutionists had entered Mexico City with the semi-savage horde of Genevo de la O. and had domiciled Obregon in the Hotel St. Francis and Pablo Gonzales in the National Palace. Following the Plan of Agua Prieta, the Congress was called in session to elect a provisional president, and on May 24 chose Adolfo De la Huerta to fill out Carranza's unexpired term of seven months. The election for the new President and Congress was also postponed from July till the first Sunday in September. Soon thereafter, all Carranza's governors and generals, who had not already turned over or been captured, tendered their submission, so that the Obregon revolution was finally achieved by June first with a minimum of bloodshed and destruction and with scarcely any damage to civilians.

Although nominally a Federal republic, under the Constitution of 1857 and even more that of 1917, the national President has found it easy to centralize the powers of the States in the Federation and to control the latter as he wished. In fact the recent imposition by Federal fiat of governors on the States of Queretaro, Guanajuato, Tamaulipas, and San Luis Potosi was one of the chief accusations brought against Carranza in the Plan of Agua Prieta. However much the President's arbitrary power may be criticized by his opponents, such power—equivalent to that of a military dictatorship—seems to be necessary if the barbarous masses of Mexico are to be kept within the bounds of a civilized order. The all-important public question then is the personality of the dictator, for upon his nod hangs the woe or weal of millions. As Pablo Gonzales has just withdrawn his candidacy, the election of Obregon is practically assured and his character thus becomes of supreme importance to everyone interested in Mexico. Will Obregon, like Carranza, continue to humor the brigand generals of the army and the grafting chiefs of the civil service; and will he likewise be helpless to restrain the bands of rebels who have infested every fertile rural district? Will Obregon also flout foreigners, especially Americans, and deride their pleas for damages by a Claims Commission that carefully files every brief but never pays a cent? Upon the answer to these questions depends the fate of Mexico as soon as the chief foreign sponsor for the Carranza government retires from office next March.

As Obregon's public career to date has been purely military data are lacking for any exact prediction as to

his reaction when invested with the civilian power. Although his troops were probably no more respectful of private property when on campaign than those of other leaders, I have no evidence that he ever used them as looters for his personal enrichment as was the practice of many of his confreres. His retirement from his high office in 1916, just when the national harvest of graft was most bountiful, indicates anyhow that avarice is not his ruling passion. Of only a mediocre education like Carranza, Obregon is free from the petty jealousy that rendered the former so incompetent as an administrator. Carranza would have no one near him whose intellect surpassed his own, and was once heard to remark: "I don't want ministers in my cabinet, but just clerks who will do my will". On the contrary, Obregon realizes his own limitations and has made his success by his wise selection of the best talent available for aids. An amateur strategist, he was yet able to beat the semi-professional army of Villa in the Celaya campaign by his practice of never making an important move without a council of war. Of proved bravery as a soldier, Obregon should carry into the presidency the courage required to suppress any malefactor however powerful—a courage that Carranza never had.

Since his recent triumph, Obregon's public statements of policy have been reassuring. He not only sustains the Plan of Agua Prieta in guaranteeing the inviolability of private life and property, but has promised to forgive all his political and military opponents except those guilty of vulgar crimes. He tells foreign investors that they will be again welcome in Mexico and assures them that those paragraphs of the new Constitution which infringe their just rights will be eliminated by legal amendment. Toward the perennial rebel political movements he has adopted a conciliating policy and has thereby done more for pacification in a few weeks than Carranza was able to do in five years with a huge army. The rebel generals, Pelaez of Vera Cruz, Mexiquera of Oaxaca, Genevo de la O. of Morelos, and Felix Diaz of the south-east coast have already laid down their arms, along with many lesser lights, and Villa seems to be the only important rebel who is still recalcitrant.

Free from avarice, competent as an administrator, courageous as a lion, friendly to foreigners, and conciliatory toward his opponents, Obregon offers every hope of being able to restore Mexico to the honored place among nations she held under Porfirio Diaz.

NICKEL-COPPER ORE to the amount of 301,133 tons was mined and 238,700 tons was smelted in Ontario during the first quarter of 1920. Shipments of matte totalling 10,168 tons were made to the refineries in Canada, United States, and Great Britain. The British America Nickel Corporation is producing matte at Nickelton and shipping to the refinery at Deschenes, Quebec. The latter is now in operation, although there was no output for the first quarter. A considerable part of the nickel oxide produced at the Port Colborne refinery of the International Nickel Co. of Canada is marketed in that form in England.

The Testing and Application of Ventilating-Fans

By WALTER S. WEEKS

DEFINITIONS. The efficiency of a machine is the percentage of the power input that is recovered in useful work; it is the useful work that it does in a given time divided by the power input.

A ventilating-fan is given credit for the static head that it produces and for the velocity-head that it produces. The pressure that a pressure-fan maintains to overcome the mine resistance is called the static pressure, and the pressure corresponding to the velocity-head which the air possesses when it leaves the fan is called the velocity-pressure. The sum of the two pressures is known as the total or dynamic pressure. The total

motor, or fan and engine, is obtained. To determine the efficiency of the fan itself a transmission dynamometer is necessary, or else the efficiency of the motor and transmission must be separately ascertained. In the following discussion I shall use the manometer readings in inches of water as a measure of head or of pressure.

A fan may be operated as a pressure-fan, as an exhaust-fan, or as a combination pressure-and-exhaust fan, so we must understand the methods of determining the total pressure under these conditions. Let us first consider the pressure-fan.

The arrangement for the test is shown in Fig. 2. The

FIG. 1. ADJUSTABLE ORIFICE

FIG. 3. VERTICAL MANOMETER

pressure multiplied by the quantity per minute in circulation gives the useful work; this divided by 33,000 is the horse-power that 'shows up' in useful work in the air.

FAN-TESTING. In order that a fan may be tested, it must be operated at constant speed under varying conditions of resistance. Tests may be run at any speed. The resistance is obtained by interposing orifices of various sizes in the duct leading from the discharge in the case of a pressure-fan; and in the duct leading to the intake, in the case of an exhaust-fan. The orifice is placed at the end of the duct. With small fans a pipe serves as the duct, and with large fans an artificial drift must be constructed. A frame in which are placed any desired number of slats is a convenient type of variable orifice. Fig. 1 shows a model of such a frame. The duct should be long enough to smooth out the eddies and establish a steady flow. The length of a circular duct is usually made 50 times the diameter.

In mining work the over-all efficiency of the fan and

adjustable orifice is at *a*. At *b* a tube is inserted with a pin-hole opening facing the side of the pipe. This tube is connected with a vertical manometer like the one in Fig. 3. The scale on the manometer is a flat 'engineer's scale' reading to decimals of an inch and arranged so that the bottom edge, which is the zero of the scale, may be set opposite the water-level in one leg of the manometer. The method of mounting the scale is shown in Fig. 4.

The Pitot-tube readings for velocity should always be taken in the duct midway between the fan and the orifice. The manometer, under the conditions shown in Fig. 2, records the friction and shock losses that the air undergoes after passing the point *b*. We credit the fan with this static pressure. In addition we must credit the fan with the velocity-head in the air at the point *b*. For example, let us suppose that the area of the pipe is one square foot and 3000 cubic feet per minute is flowing. The manometer reads 4 in. The weight of one cubic foot of air is 0.08 lb. Let us determine the

total pressure and the horse-power in the air.

The velocity is 50 ft. per second.

$$\text{Velocity-pressure} = \frac{w v^2}{2g} = \frac{0.08 \times 2500}{64} = 3.12.$$

Velocity-pressure = 3.12 lb. per square foot.

$$\text{Velocity-pressure in inches of water} = \frac{3.12}{5.2} = 0.6$$

Total pressure in inches of water = $4.0 + 0.6 = 4.6$.

Total pressure in pounds per square foot = $4.6 \times 5.2 = 23.9$.

$$\text{Horse-power} = \frac{23.9 \times 3000}{33,000} = 2.2.$$

Let us consider next the exhaust-fan arranged as in Fig. 5. The manometer is connected at *a*. The pressure at *a* will be below that of the atmosphere. Conditions are quite different from the case we have just discussed. In the case of the pressure-fan, the pressure recorded by the manometer did not cause the air to flow; it did not impart the velocity-head to the air; the air received its velocity in the fan before it reached the manometer, so the reading did not include the velocity-head.

In the case of the suction-fan, the atmospheric air is still. The fan produces a depression, and this depression, or difference in pressure between the outside air and the fan-inlet, must not only overcome friction but it must supply the velocity-head to the still air when it enters the pipe. A manometer arranged on an exhaust-fan as in Fig. 5 records the total pressure produced by the fan.

The fact to fix in the mind is this: if the pressure measured causes the flow, the velocity-pressure is included in the manometer reading. If we had a pressure-fan arranged as in Fig. 6, where the air is brought to a negligible velocity before entering the pipe, the manometer would record the total pressure, because the only source of velocity would be the pressure in the chamber. The usual arrangement of a pressure-fan is that of Fig. 2, where the manometer does not measure the velocity-head. Now let us attack the problem of a combination pressure-and-exhaust fan.

There are three subdivisions under this head that demand attention. The discharge-pipe is (a) the same size as the suction-pipe, (b) smaller than the suction-pipe, or (c) larger than the suction-pipe. Two manometers are necessary, one at the inlet and one at the discharge. We must be careful that we do not credit the fan more than once with the velocity-head. Let us consider the condition where both pipes are of the same size. The velocity-head in the discharge-pipe is the same as that in the suction. The manometer on the suction gives friction and shock losses in the suction-pipe, and velocity-head in the suction-pipe. The manometer on the discharge-pipe gives friction and shock losses in the discharge-pipe, so the sum of the two manometer readings is the total pressure produced by the fan.

If the discharge-pipe is smaller than the suction-pipe, there has been a gain of velocity-head. The fan must be credited with this gain. An example will illustrate: The suction manometer reads 3 in. and the discharge manometer 4 in. The size of the suction is one square

foot, and that of the discharge is half that; 3000 cu. ft. per minute is circulating. Weight of air is 0.08 lb. per cu. ft. Determine the total pressure.

The sum of the water-gauges is 7 in. This includes friction in both pipes and velocity-head in the suction. The velocity-head in the suction is 0.6 in. The velocity in the discharge is twice that in the suction, so the velocity-head in the discharge is four times that in the suction, or 2.4 inches.

The gain in velocity-head is $2.4 - 0.6 = 1.8$.

So the total head is $7 + 1.8 = 8.8$ inches.

If the discharge-pipe is larger than the suction-pipe, it is assumed that the fan has recovered some of the velocity-head of the suction-pipe, therefore the decrease in velocity-head is deducted from the sum of the two manometer readings.

In all cases the horse-power in the air is computed by the formula:

$$\text{Hp.} = \frac{P Q}{33,000}$$

P = Total pressure in pounds per square foot.

Q = Quantity in cubic feet per minute.

In running a complete fan-test, the orifice is first entirely closed, and the pressure readings taken. Air is then admitted in stages, and at each stage the quantity is determined with the Pitot tube, and the pressure readings and power measurements are taken. With these data the working characteristics of the fan may be plotted.

With cubic feet of air per minute as abscissae, we may plot curves of static pressure, total pressure, velocity-pressure, and efficiency.

THE EQUIVALENT ORIFICE OF A MINE. In the fan-test the resistances interposed are orifices of various sizes. If we know the pressure necessary to overcome friction in a mine when a given quantity of air is flowing, we can calculate the size of the orifice that will offer the same resistance. Such an orifice is called the 'equivalent' orifice of the mine. The conditions that exist when a fan is connected with an equivalent orifice may be represented by Fig. 2. The fan will maintain some pressure in the pipe. Air will flow out through the orifice according to the law $v = \sqrt{2gh}$. The static pressure-head in front of the orifice is first converted into velocity-head and the air flows through the orifice. When it meets the still air outside, the velocity-head is destroyed by shock. The actual pressure that causes the flow through the orifice is the static pressure plus the velocity-pressure in the air as it approaches the orifice. This velocity of approach is ordinarily so small that it may be neglected, and the flow calculated as if it were due to the static pressure alone.

Let *A* be the area of the orifice to be determined.

v = Velocity in feet per second.

q = Quantity in cubic feet per second.

$$v = \sqrt{2gh}$$

$$A v = q.$$

When air flows through an orifice under a constant head, the area of the stream contracts so that the actual

amount flowing is only 64% of the theoretical amount.

$$q = 0.64 A \sqrt{2gh}$$

$$A = \frac{q}{0.64 \sqrt{2gh}}$$

Let Q = quantity in cubic feet per minute.

i = pressure in inches of water.

0.075 lb. = weight of one cubic foot of air.

$$\text{Then } A = \frac{0.0004 Q}{\sqrt{i}}$$

Fig. 2

Example: It requires a water-gauge of 4 in. to force 100,000 cu. ft. of air through a given mine. What is the equivalent orifice?

$$A = \frac{0.0004 Q}{\sqrt{i}}$$

$$A = \frac{40}{2} = 20 \text{ sq. ft.}$$

The principle of the equivalent orifice may be used to determine whether a fan will accomplish a given result. For example, suppose that you wish to force 3000 cu. ft. per minute into a pipe in a drift and it requires 12 in. of water to do it. You have on hand a fan that you would like to use. Connect a pipe and orifice to the fan.

Fig. 4

Close the orifice until the pressure rises to 12 in. (if it ever does) and measure the air. If 3000 cu. ft. or more is passing, the fan will do the work. If the fan when running at the maximum speed never gives a water-gauge of 12 in., or if when the water-gauge is 12 in. less than 3000 cu. ft. is passing, the fan will not do. Such a short-cut method would not be used in selecting a big fan because the efficiency of the operation must be considered carefully.

THE DOOR-REGULATOR. The approximate opening of a regulator in a mine-door is figured in the same manner as the equivalent orifice. It will be recalled that the resistance of a split must often be increased to prevent too much air from passing through the split. Let us see how the regulator destroys pressure. Referring to Fig. 7, a given quantity of air is circulating in the drift with a velocity of V feet per minute. In a door a is an orifice the size of which is controlled by a sliding gate. The

velocity increases when the air passes through the orifice. This increase in velocity-head is accompanied by a decrease in pressure-head. If this increase in velocity-head is then destroyed, we have thus destroyed a certain amount of static pressure. The velocity-head in the drift itself is usually so small that it may be neglected. That being the case, the size of the opening of a regulator necessary to destroy a given amount of static pressure may be computed with the equivalent orifice formula.

$$A = \frac{0.0004 Q}{\sqrt{i}}$$

In this case i is the number of inches of pressure that we wish to destroy. After the air passes through the regulator at high speed it strikes the slow-moving air in the drift, and swirls and eddies until it finally slows

Fig. 5

Fig. 6

down to the normal speed of the drift. This formula is used to determine the approximate size of the regulator, and then it is adjusted until the correct amount of air is shown by the anemometer. Example: the resistance of a drift when 15,000 cu. ft. per minute is flowing is two inches. The resistance must be increased to 4.25 in. with the same amount of air. Determine the regulator opening.

The regulator must destroy 2.25 inches.

$$A = \frac{0.0004 \times 15,000}{\sqrt{2.25}}$$

$$A = 4 \text{ sq. ft.}$$

CHANGES OF VELOCITY. In the first article of the series* we studied the friction of the ventilating air and we saw that we must apply enough static pressure to overcome the friction of the circulating air. We must do more than this; we must supply enough additional pressure to account for such increases in velocity as may take place.

*M. & S. P., April 24, 1920.

Consider Fig. 8. Suppose air is moving 500 ft. per minute in the drift *AB*. The area of *BC* is half the area of *AB*, so the velocity in *BC* is 1000 ft. per minute. This increase in velocity-head must come from the static pressure at *a*, so the static pressure at *b* will be less than the static pressure at *a* by an amount equal to the gain in velocity-head. Now, when the stream of air enters *BC* it contracts, so the speed at entrance must be greater than the speed after the air fills the whole drift. When an orifice such as the opening of a drift or shaft is followed by a duct of the same size, the coefficient of contraction is about 0.82, so the velocity-head at the entrance will be 1.5 times the velocity-head in the drift after the air fills the drift. So half the normal velocity-head in the drift *BC* is lost in shock at the entrance. If the

Fig 7

Fig. 8

Fig. 9

change in size were made gradually, this shock loss would not occur.

If the drift *BC* opens into a larger drift, the fast-moving air in *BC* strikes the slow-moving air in *CD* and the difference in these two velocity-heads is lost in shock. If the change were made by a gradually expanding cone, part of the velocity-head would be recovered and the static pressure at *d* would be greater than the static pressure at *c*. In practice, however, no velocity-head would be recovered because no attempt is made to save it. So if the velocity increases we must add the increase in velocity-head to the mine resistance; if velocity decreases we neglect it. Let us now take a short example of selecting a pressure-fan for a small mine considering the changes of velocity. See Fig. 9.

The fan situated at *A* is to force 50,000 cu. ft. of air through the openings as shown. The friction is first calculated, and this is given in inches of water below the drifts. The figures in the drifts indicate the velocity of the air in feet per minute. The problem is to determine the water-gauge at which the fan must operate.

Assuming that an air current with a velocity of 4000 ft. per minute has a velocity-head equivalent to one inch of water;

Increase in velocity-head at <i>B</i>	$1.5 \times 0.063 - 0.016 = 0.078$
Decrease in velocity-head at <i>C</i>	(neglect)
Increase in velocity-head at <i>D</i>	$1.5 \times 0.076 - 0.01 = 0.104$
Total increase in velocity-head	0.182
Friction	3.75

The fan for this mine must be able to supply 50,000 cu. ft. of air per minute at a static pressure of 3.93 in. of water.

If there are but few velocity changes, they may be neglected, but if there are many in series, their sum may be appreciable.

Now let the fan be an exhaust-fan situated at *E*, with the air circulating as before. We must now maintain a slightly greater difference in pressure between the two ends, because it is now necessary to give velocity to the still air outside in order to make it enter the mine. The velocity in the first drift is 500 ft. per minute. This is equivalent to 0.016 in. of water. The velocity-head at entrance is

$$1.5 \times 0.016 = 0.024$$

Since the velocity-head outside is zero, this is the gain in velocity-head.

The suction-fan must maintain at the fan-inlet a static vacuum, as it is called, of

$$3.93 + 0.024 = 3.95 \text{ in. of water.}$$

A manometer at the fan-inlet of an exhaust-fan measures friction and all the velocity changes that take place from the still air outside. A manometer at the discharge of a pressure-fan measures friction and all the velocity changes that take place after the air has passed the manometer. It does not measure the velocity-head in the air in the first drift. The air possessed this velocity before it reached the manometer.

HIGH-PRESSURE FANS. Up to the present we have been dealing with fans that supply a large amount of air at low water-gauge. This sort of fan is adapted to mine ventilation when the ducts are the ordinary mine openings. There is another type of ventilation no less essential, namely, the ventilation of drifts and tunnels while they are being driven. For such work, a pipe-line is run from the entrance to the breast and the air is either forced in through the pipe or sucked out through the pipe. Such a ventilating system demands a much higher pressure; for instance, to force 2000 cu. ft. of air per minute through a 12-in. pipe 4000 ft. long requires a pressure of about 40 in. of water.

Ordinary centrifugal blowers can be obtained that will deliver at pressures up to 1.5 lb. per square inch. To obtain pressures above this we must use a centrifugal compressor or a positive-pressure blower. A centrifugal compressor is built much like a high-grade turbine-pump with diffuser-vanes. A single-stage centrifugal compressor may be obtained to give pressures up to 4 lb. per square inch.

In tunnel work it is often desirable to reverse the air current. By means of a 'four-gate system' either the discharge or the inlet can be connected to the pipe. With high-pressure fans or centrifugal compressors, a smaller water-gauge will be produced when the fan is exhausting than when it is blowing, provided the speed and quantity be the same. This is because the density of the air handled is less when the fan is exhausting.

If the pressure that a fan or centrifugal compressor will produce when blowing is known, the suction-pressure

that the machine will produce may be computed by utilizing the simple rule, that with a given speed and quantity the ratio of the absolute discharge-pressure to the absolute inlet-pressure is a constant.

Let P be the absolute discharge-pressure.

Let P_1 be the absolute inlet-pressure.

Then $\frac{P}{P_1} = C$

Example:

A fan blowing gives a pressure of 40 in. of water. What suction-pressure will it create when exhausting?

Let the atmospheric pressure be equivalent to
407.2 in. of water.

Conditions when blowing.

$$P = 40 + 407.2 = 447.2$$

$$P_1 = 407.2$$

When exhausting, P will be at atmospheric pressure, and P_1 will be determined.

$$\frac{447.2}{407.2} = \frac{407.2}{X}$$

$$X = 370$$

$$407.2 - 370 = 37.2$$

So the suction-pressure is 37.2 in. below the atmosphere.

A centrifugal compressor gives 4 lb. per square inch in blowing. What negative pressure will it create?

Assuming that atmospheric pressure is 15 lb. per square inch,

$$\frac{19}{15} = \frac{15}{X}$$

$$X = 11.8$$

$$15 - 11.8 = 3.2$$

The negative pressure produced when exhausting will be 3.2 lb. per square inch.

[This is the fourth of a series of articles by Professor Weeks on the ventilation of mines. The first article appeared in the issue of April 24, the second in that of June 12, and the third was in the issue of June 19.—EDITOR.]

Manufacture of Aluminum

The possibilities of manufacturing aluminum by hydro-electric means at The Dalles, Washington, is discussed in Bulletin No. 5 of the Engineering Experiment Station at the University of Washington by Charles D. Grier. The manufacture of aluminum requires two steps: the preparation of pure alumina, the oxide of aluminum, from the ore, bauxite, and the solution and electrolysis of this alumina in a bath of molten cryolite, resulting in the deposition of molten aluminum at the bottom of the bath. Bauxite, which is the natural hydrated oxide of aluminum, is never pure enough as mined to be used without purification. This is accomplished by calcining the ore, dissolving in caustic soda, precipitating alumina from this solution, and calcining the resulting precipitate. This purified alumina is then fed at intervals into a bath of used cryolite which is contained in a box-like furnace or pot, the bottom of

which acts as a cathode. The anodes are specially prepared amorphous carbon blocks suspended in the bath, and are gradually consumed by the oxygen liberated. The bath is kept molten by the heat generated by the passage of the current. The raw materials required for the manufacture of aluminum are bauxite, coal, and caustic soda for purifying it, cryolite, and carbon in some form (usually as petroleum-coke) for making electrodes. There are no bauxite deposits of large size known in Western States. If domestic ore were to be used in a plant in Washington, it would be necessary to procure the ore from the Eastern deposits, those in Arkansas being the nearest and also of the highest grade. Large deposits of high-grade bauxite were being opened up in British Guiana before the War, and a considerable amount of this material has been used at the Soller's Point plant of the Aluminum Company of America, in Maryland. Permits for developments beyond those then licensed were not granted by the British government during the War, and it is said that operations in the future are to be governed by the policy of conserving the mineral wealth of the British Empire for itself. If these deposits become available they might be a very attractive source of raw material for an aluminum plant on the Pacific Coast. Deposits of bauxite are also found in Dutch Guiana. India produces bauxite of high grade, and ore from that source might also be available. These latter sources involve ocean transportation, however, and although this may be an advantage when the shipping industry becomes more nearly normal, it is thought best not to consider the use of these ores in this discussion. Cryolite is mined in Greenland, which furnishes the world's supply. It is possible to substitute an artificially made fluoride of aluminum and sodium; this is done to some extent by the European manufacturers. Coal and caustic soda for bauxite purification are readily available both in Arkansas and in Washington; purification of the bauxite at the mine would, however, save freight. Petroleum-coke is readily available from the oil-refineries; charcoal could also be readily obtained if a steady and reliable demand for it were assured.

The production of aluminum in the United States in 1917 was estimated to be 200,000,000 lb., which is nearly triple the production in 1913. The average yearly increase since 1913 in the annual production was about 34,000,000 lb. The 1917 production may be taken as a measure of the capacity, for all plants were working at full capacity. It is stated that this capacity will be doubled by the completion of the plants of the Cheoah Aluminum Co., a subsidiary of the Aluminum Company of America, thus making the producing capacity roughly four million pounds per year. It is difficult to forecast future consumption, but it is evident that the present American producer is providing ample capacity to take care of a great expansion of demand, and that any new company entering the American market would have strong competition. The conclusion is that the erection of a plant on the Pacific Coast at the present time is not justified.

The Ore Deposits of Mexico—IV

Ore Deposits in Limestone and Not of Direct Igneous Origin

By S. J. LEWIS

INTRODUCTION. In the foregoing articles I have discussed Mexican ore deposits in sedimentary rocks in which a close association can be established with igneous intrusives. There is a large number of mines in Northern Mexico where such an association cannot be proved. In this class of deposits, confined exclusively to the base metals, nearly every condition is similar to those found in the other classes of orebodies, except for the lack of an igneous rock in contact with the mineralization or close to it. In this class the sediments are disturbed, broken, and highly altered in the immediate neighborhood of the orebodies as by hot solutions and vapors. The ores themselves, with their gangue, are in all important respects similar to the products of mineralization in the cases of admitted igneous influence. Hot or tepid mineral springs in the neighborhood of some of these deposits give evidence of expiring vulcanism, establishing the existence in the locality of a deep-seated source of magmatic emanations. While exploration in most of these will probably never go deep enough to prove such igneous connection, the inference is warranted that igneous intrusives, buried under the sediments, are the ultimate source of the hot solutions that mineralized these deposits, at least as regards the primary ores. In most of these cases, pay-ore has been made largely by oxidation due to secondary agencies.

THE CABRILLAS GROUP. This group of lead-zinc-iron mines, comprising the Cabrillas, Palomas, and Higuera properties, besides adjoining prospects, are in the State of Coahuila, mid-way between Monterrey and Saltillo. They are of comparatively recent discovery, having risen to importance owing to the requirements of local smelters for fluxing ores. The ores are oxides of lead, iron, and zinc, the last occurring in large and profitable bodies in the Palomas. Unoxidized cores of galena are common in specimens of the better ore.

"The limestone ridge in which these orebodies occur has a general east and west axis, with spurs radiating northward into the valley. The mineralization is in a belt of black, shaly, badly-crushed limestone."¹⁷ The ores were deposited in pipes or chimneys, in open or in partly open caves, and as replacements of strata connected with the chimneys, all along the great fracture that goes through the mountain from the Cabrillas to the Palomas side and through to the Higuera mine across the next arroyo. This great fracture is the arresting feature of the deposits. From the Palomas side it shows

up well, with the heavily folded strata changing rapidly from the nearly horizontal position where undisturbed to the steep inclination into which the movement pushed them. It is a typical break like that with which similar deposits are so often associated in Northern Mexico, its special feature being great size. No intrusive igneous rock is known in the immediate neighborhood. The adjacent hills, which show no signs of fracturing, do not contain ore deposits, so far as known. The known ore is bottomed by a thick sheet of highly altered rock made up principally of gypsum, the full thickness of which has never been determined. When the deposits are followed down to this gypsum formation their richness diminishes, finally to extinction, the fracture meanwhile pinching to a small crack that cannot be followed.

In every essential feature, except the visible presence of an eruptive or intrusive rock, the deposits are similar to typical contact orebodies in limestone such as those we have been discussing. We have a huge channel through the limestones, at high angles to the bedding-planes, with the sediments sloping away from the fractures on both sides. We have the oxidized ore deposited along this channel, replacing the lime strata in some places and filling open spaces in others. We have the highly-altered "black shaly" limestone in the immediate vicinity of the orebodies, although the country-rock is the ordinary blue limestone of the Cretaceous. Such alteration is very suggestive, like the other conditions, of a deep-seated source, from which mineralizing solutions worked their way up and caused deposition in the fracture. As has been said in a somewhat different connection, "the cause is found at some point below the effect, pointing to a reaction between an ascending mineralizer and the limestone."¹⁸ The only cause that could satisfy the conditions of the problem would seem to be a deeply-buried intrusive mass, whose forced entrance into the ground would be amply sufficient to cause the fracturing, and from which the mineralizers have since made their devious way upward. In no other way can this local break be explained: regional folding in the general course of mountain-making could hardly have made such a fracture system and left everything in the immediate neighborhood practically undisturbed. In shape, size, orebodies, and general features, the deposits belong to the contact group, except for the unknown intrusive.

MITRA MOUNTAIN. Similar low-grade lead-iron ores were found in considerable tonnage in Mitra mountain near Monterrey, some twenty-odd years ago and a good

¹⁷Lewis, S. J., 'Cabrillas Lead Mines', 'E. & M. J.', Vol. 89, p. 1071.

¹⁸Prescott, Basil, 'Economic Geology', Vol. X, p. 61.

deal of it has been used by local smelters. The mountain gets its name from the striking resemblance its three-pointed crest bears to a bishop's mitre, when seen from the city. Monterrey stands on a little plain, hemmed in by high mountains carved out of the limestone strata. Like them, the Mitra rises almost sheer from the flat; on closer acquaintance, it turns out to be much longer than one would suppose in viewing it from the city, and to be approachable on the west side by small foothills that break the ascent. On the east it is all but insurmountable for the average climber. As in all this region, the folding has been severe, and erosion has usually cut through the upper parts or anticlines. The mitre-shaped crest is formed by blocks of the anticlines left as small spires; in most of the surrounding mountains, such spires have been removed, leaving only the sharply-tilted strata of the hillsides, with the domes cut off, so that the ends of the beds go down on the opposite sides like huge irregular steps. The Mitra is a conspicuous exception; it shows a gently-sloping dome on its longer axis, broken here and there by transverse fractures, and capped by the spires remaining from the uppermost strata. Its summit is over 5000 ft. above sea-level.

The ore deposits are of the red-dish-brown earthy oxide type, with a little lead, a few hundred grammes of silver, considerable iron, and a low percentage of insoluble: hence 'neutral' or better, and desired by the smelter. The ore occurs in irregular bodies, filling caves in the limestone along a line of fracturing, or replacing certain strata. In the former case, the trail of mineralization can generally be followed, with patience and skill, from one cave orebody to the next; in the case of the blanket deposits, the mineralization generally can be traced from one of the dominant fractures, as in the true contact deposits. The most important feature of the Mitra deposits is the fact that all pay-ore to date has been found in strata of dolomitic limestone near the crest of the mountain, where the fractures go through them. Above this dolomite horizon, only low-grade iron ores have been found, exclusively in the anticline. There is considerable dissemination of galena crystals in the limestone above the ore-horizon. No heavy fracturing is visible at any point. Nevertheless, lines of weakness at the anticlinal folds have served as channels for mineralizers from below, where solutions could react with the wall-rock, widening the channels and depositing the mineral. See Fig. 15.

The accepted theory for the origin of these deposits, based on J. E. Spurr's work in 1906 in the Diente deposits on the other side of the city, shows that the metallic minerals were precipitated out of solution by the selective action of certain sediments in which fossils are especially abundant. A similar action will be shown to have influenced the deposition of antimony ores at Wadley, south of Catorce. The present paper is more especially concerned with the origin of the mineral-bearing solutions that found their way into the favorable horizon.

FIG. 15. LA MITRA

In accord with the views herein expressed, their origin must be sought in deep-seated igneous bodies lying below the limestone. There is no intrusive structure visible anywhere near the deposits, and the lines of circulation in the anticlinal domes may have originated in the crumpling and folding of the sediments. The origin of the mineral that in one form or another found its way into these channels is, however, a more difficult matter to determine.

The precipitation products of similar solutions will be similar; if the ores of various deposits are closely alike, it would certainly seem that the original solutions from which they came could not have differed markedly. All of these lead-zinc deposits in Northern Mexico have much the same features of occurrence and mineralization as are found in the numerous lead-zinc deposits in the same region where the intrusive is known to exist. For ex-

ample, the principal structural difference between these Mitra deposits and those of the Santa Rosa range near Muzquiz, State of Coahuila, is that, in the latter, evidences of vulcanism are abundant, instead of being deeply buried as in the Mitra. The Cedral mine, for instance, in the Santa Rosa area, is on a fracture showing a strik-

The one visible structure of igneous origin in the district is the vast field of granite, which outcrops about 30 km. north of Topo Chico and is such a prominent feature of the Bustamante and Villaldama topography. The in-

FIG. 16. WADLEY ANTIMONY MINES

ing resemblance to the Cabrillas fracture. At Topo Chico, a few kilometres from the Mitra, profitable deposits of lead and zinc have been found in ground entirely like the Mitra formation; with the difference that the mineral springs close-by suggest a connection with underground sources of mineralization. The fact is that in all these mines, the ore occurs either in fractures or close to them in the anticlines, not disseminated over

FIG. 17. COLA DE ZORRA MINES

fluence of this intrusive mass would be quite sufficient to account for the neighboring ore deposits; and it would seem entirely probable that similar occurrences of gran-

FIG. 18. THE SANTA MARIA ANTIMONY MINES

undisturbed areas. The most satisfactory hypothesis of origin would allow for the existence during some bygone period of deep-seated mineralizing influences that became effective through the dislocation of the strata.

ite, related to the Bustamante rock, underlie the Monterrey lead-zinc district and are responsible for the mineralizing emanations that made their way up to the limestone and deposited the ore.

The antimony deposits near Wadley, in the State of San Luis Potosi, have been mentioned as showing the influence of the organic remains due to fossils on ore deposition in adjoining strata. They furnish an interesting example of mineralization in limestone clearly to be ascribed to mineralizers from deep-seated sources, yet which cannot be connected directly with any near-by volcanic mass. The district is 16 km. south of the Catorce Real, hence it is an outlier of the andesite-limestone contact district of Catorce. The only volcanic rock I have seen near the Wadley deposits is found in arroyos at the southern end of the district, where dikes of reddish-brown doleritic rock appear crossing the formation. The antimony mineralization is entirely in the blue limestone high on the mountain wall, and shows no admixture of any common metal or of gold or silver. A little cinnabar is frequently found coloring the antimony crystals, and in certain veins carrying no antimony a little lead has been observed. As a whole it is strictly an antimony deposit, the ore occurring chiefly as replacements in certain strata, but the mineralization nearly always proceeds outward into those strata from vertical fractures crossing the formation.

The principal mines are at Tierras Prietas, near San Jose village, 8 km. east of the railway station at Wadley. In these the ore occurs in each of three parallel and nearly vertical fissures, running nearly north and south for a distance of over a kilometre, and cross-faulted in two places, the displacement being but a few metres eastward. The strata are nearly horizontal at the top of the mesa, and at a short distance below the surface some of them have been extensively replaced by irregular bodies of antimony, usually in crystalline form, penetrating the limestone. The accompanying photograph (Fig. 16) shows the two principal blankets, crossed by the Treinta-y-Uno cross-vein, all heavily ore-bearing. The principal lode, already mentioned, makes another set of crossings with these, as it runs parallel to the edge of the mesa.

These deposits have been partly mined to a depth of 100 m. below the outcrop, there being as yet no change observable in the ore in that depth. The ore is antimony oxide, chiefly valentinite, usually in fine crystal aggregates. Individual crystals are sometimes ten to twelve inches long. Stibnite is occasionally found, also crystalline, and nearly all the oxide crystals have a core of sulphide. A good deal of the product is in the form of amorphous mineral taken out as an earth of rather lower grade than the coarse ore. Oxidation has certainly been very thorough in these deposits, yet the evidence of the original sulphide deposition is indisputable.

A striking and noteworthy feature of the deposits is the occurrence of especially good orebodies at the intersections of vertical fractures with certain strata having a favorable chemical reaction. The accompanying sketches (Fig 19) show the mode of occurrence of the ore under variants of these conditions. Several cases show fine bodies in the anticlinal folds where cut by a vertical fracture; others in the syncline where cut in the same way; and still others in practically level horizons. In every

case, the richest ore is found in the vertical fissure, diminishing in quantity and grade as it goes outward from the fissure and penetrates the strata. It is evident that the ore deposition was principally from magmatic vapors under high temperature, which carried in the antimony in a state of volatilization, and which dropped their metallic burden under certain conditions of temperature and reaction with the strata. Whatever the cause of the fracturing, the mineral must have come from a source of great heat and pressure, corresponding to some deeply-buried volcanic mass, in which the antimony minerals

FIG. 19

were differentiated at a late period of magmatic segregation, and discharged in gaseous solution.

At the Cola de Zorra mines of this group, at the northerly end of the district, there has been a striking mineralization of the limestone strata adjoining a narrow belt of sandstone and clay, about 30 ft. thick, in which fossils abound, chiefly small clams. I have traced this fossil horizon south to the Tierras Prietas mines, always immediately above the mineralized strata; however, it is nowhere so clearly defined as at the Cola de Zorra. The photograph (Fig. 17) shows the string of mine openings in the strata immediately below the sandstone. The replacement of lime by antimony is extensive through these strata, vertical fractures showing occasionally as in the Tierras Prietas deposits. The strong twisting to which the whole structure has been subjected, giving heavy folding of the limestones, makes the ore-occurrence very striking, with the sandstone beds on top, the ore-bearing strata below, and a stratum of black, hard, silicious limestone, highly altered, below that, all three formations following the regional folding faithfully. It is quite evident that here, as in the dolomite horizon at

the Mitra or in the lead-iron mines of the Diente, the organic remains contained in the sandstone exercised a precipitating influence on the solutions circulating in their vicinity. It seems equally evident from the testimony of the ore-occurrence in the vertical fractures, with enrichment at the intersections with certain strata and dying out with distance from the fissures, that the solutions and vapors carrying the primary mineral had an igneous origin. With metals so easily volatilized as antimony and the mercury that frequently colors it, it may be assumed that the primary deposition was effected from gases. The comparatively short distance of the deposits from the enormous igneous structure of the Catorce district; the presence of the dikes in the Wadley arroyos, in connection with the important part played by the dikes of Catorce, all point to a regional relation to the Catorce deposits. In the last analysis, the antimony orebodies at Wadley, deposited in cracks made in the strata through the general processes of mountain-making of the area, are to be considered as evidence of dying vulcanism, which in its earlier stages made the lead-silver deposits of Catorce, and originated, like the latter, in the magmatic gases and waters discharged from the igneous rock-mass.

SUMMARY. In the foregoing examples, we have begun by considering true contact deposits, in which the igneous origin of the orebodies can be conclusively demonstrated, and have ended with others in which such igneous origin could only be deduced by analogy; the most striking feature of the study, as a whole, is the practical identity of the ores in the true contact class with those we have just reviewed. This feature seems to me of the greatest importance in its suggestion of a common origin for all these ores.

Steaming Amalgamating Plates

Under certain conditions the removal of amalgam from plates requires a good deal of labor, unless steam is used to soften the deposit. A plate which has a comparatively large amount of amalgam left on it will be capable of receiving a liberal amount of mercury when dressing and will remain soft and in good receptive condition longer than a comparatively bare plate under the same conditions. To preserve this quality such plates will be scraped but lightly, and the result is an accumulation which produces a high steaming-return. The man who adopts this method will obtain a high return by amalgamation, but will probably be accused of holding gold back, and may be reckoned a culprit as far as advocating steaming is concerned. The next example may be taken where a similar condition of plate is arrived at with a minimum of amalgam left. This will require more frequent dressing to prevent hardening, and hard scraping every day; probably also a thorough scouring every other day. This will also give a high amalgamation return with a maximum of labor and the conscience rectitude of a humanitarian who does not advocate steaming. A variety of the foregoing is found where the plan is to scour less often, but make a big job of it once a month, in place of steaming. Another variety of method is adopted by one

group where a decrease in mercury consumption is effected by the use of blankets. It is not proposed to go further into methods, because a difference of opinion exists as to whether a high extraction by amalgamation is desirable or not, in view of the labor required and the idle capital involved in laying out the plant.

Variety exists in the ratio of water to rock crushed. On the one hand we have a plant with launders having insufficient grade, where the water-ratio is necessarily high. On the other hand, we have a more modern plant with probably excess launder-grade, but economic in plate-area. In the first case we may have a ratio of perhaps 8:1, and in the second as low as 2:1. These differing conditions will affect the grade of the plant—18% being necessary in the one case compared with 8% in the other. Apart from the overcrowding of the plate-area, this extra grade causes difficulty in control of the plate-condition. With a bare plate there is nothing to arrest the mercury in its tendency to roll off into the launder, so a choice has to be made as to leaving a deposit or very frequent dressing. In any case amalgam at the top of the plate will harden more rapidly and require removal with more labor whether by steaming or by other means. The degree of alkalinity of the mill-water affects accumulations on the plates in that an excess of lime hardens the amalgam. The fineness of the gold amalgamated is also a minor factor; coarse gold particles do not accumulate and are not difficult to remove, but the reverse is true of the finer particles. Dealing with the facts as they are interpreted by S. H. Pearce and T. E. Thomas, according to a statement quoted in the 'Financial Times', steaming can only be considered as a labor-saving device which enables plate-accumulations to be removed with the least difficulty, as otherwise, in the absence of a mechanical device to take its place a large expenditure of labor would be incurred in most instances. In the absence of medical evidence to the contrary, they do not consider, if proper precautions are taken, that steaming should not be continued. The precautions advised are well known to everyone, and are: Provide ample ventilation for plate-houses; lead exhaust-steam from plates to the outside of the building; select men for the operation who are known to be immune; divide the work as much as possible, to avoid over-exertion; provide wash-basins and mouth-washes for the workmen.

MANGANESE ORE assaying 40% has been produced from the Three Kids property near Las Vegas, Nevada. The method of mining the orebody is simple. An overburden from 2 to 12 ft. thick which directly overlies the deposit is broken up and removed by horse-drawn scrapers; the ore is then mined by the open-pit method. The deposit is drilled from the top, and with each round of blasts a great quantity of ore is broken down. The fragments of ore are generally of large size. Large pieces may be handled with little difficulty because of the low specific gravity of the ore, but where necessary the fragments may be reduced by chopping with axes and streaks of sand that adhere to some of the ore may be scraped off with small hand-tools.

The Scope of Work of the Bureau of Mines

By VAN. H. MANNING

Under the organic act establishing it, the Bureau of Mines is authorized to conduct investigations designed to improve health and safety conditions in the mineral industry and to promote efficient development and utilization of our mineral resources. The field of the Bureau's activity, therefore, begins with the commercial development of mineral deposits and ends with the production and utilization of the final marketable product.

In order to serve more efficiently the various sections of the country, the Bureau has established, in addition to its main offices at Washington, D. C., eleven field experiment stations, three field-offices, and several mine-rescue cars and mine-rescue stations. These field-branches are so distributed as to cover most of the mining districts of this country, including Alaska.

The Bureau is prohibited by law from doing work exclusively for the benefit of any private company or individual. Generally speaking, the Bureau does no assaying, ore-testing, or similar service work for the benefit of private companies or individuals. In response to requests for work of this sort a list of assay and ore-testing laboratories is supplied. In referring inquiries to commercial laboratories or consulting engineers, care is taken to mention several names so as to avoid designating any one establishment or engineer.

Samples are frequently brought-in to the Bureau stations or received by mail with a request for identification or analysis. If identification requires only a few minutes, the information is furnished by the station; samples for analysis are sometimes referred to the State mining bureau, State university, or similar agency if they are equipped to do such work. An occasional chemical test or determination is made as a matter of courtesy; sometimes the facilities of Bureau laboratories are placed at the disposal of an individual desiring to make some test. These are the exceptions and not the rule, as this interferes with regular work and should be avoided wherever possible. In the matter of furnishing information and professional advice, the stations and field-offices have, in addition to Bureau publications, technical libraries and catalogue-files which are available to the public. The main files of technical information regarding the mining industry are kept in the Washington office. In replying to requests for assistance or advice in regard to developing a property or carrying out some metallurgical experiment or operation, an effort is made to analyze the problem and indicate the scope and character of the work which is involved and the type of professional assistance which is needed. In other words, the endeavor is to suggest the means of obtaining the information or assistance desired. This practice applies particularly to cases where an opinion is desired in regard to a mineral deposit

or metallurgical process and where the person making the inquiry has an incorrect impression as to the amount of work involved in a mine-examination or in determining the value of a process for ore-treatment.

Under Bureau regulation, no regular salaried employee is permitted to do private consulting work, except in some cases of arbitration; he is expected to devote his entire time to the work of the Bureau, and in discussing the work of the Bureau staff, therefore, I am considering only the work of the organization.

Apart from certain administrative duties specifically assigned to the Bureau by Congress, the function of the Bureau is regarded as essentially investigative and educational. From this standpoint many of the projects undertaken are in the nature of pioneering; it is expected that some of these which develop favorably will be taken up by private interests and carried forward by them to their ultimate completion or application. In fact the smallness of the appropriation for Bureau work as compared with the field which demands attention, makes it necessary to pursue a general policy of continuing any given activity only so long and to such an extent as is necessary to secure the active interest and co-operation of the commercial organizations or individuals most concerned. In other words, we aim to avoid duplication and, whenever possible, competing in any work that is being effectively handled by any private or governmental organization. This does not mean, however, that the Bureau will not take an active part in matters which are receiving attention from private interests, as in all cases our fundamental purpose is to promote the rapid development of those things which will be of value to the mineral industry.

In the choice of subjects for investigation, the extent to which public interest is involved is a fundamental consideration. The way in which activities may be segregated on this basis can be illustrated by the following diagram:

Governmental activities for benefit of the public		Activities of companies and individuals for private benefit	
A. Clear Field		B. 'Twilight Zone'	
1. Matters of public interest only, no private interest being involved.		1. Matters in which private interest is equal or subordinate to public interest.	
2. Matters in which the public interest is paramount to private interest.		2. Matters in which private agencies are not qualified or lack the necessary equipment and which have enough public interest to justify governmental assistance.	
		C. Clear Field	
		1. Matters in which the public has no interest.	
		2. Matters in which the public does not need to be considered.	

An illustration of matter falling in the first sub-division of class A is the testing and inspection of fuel purchases by the Government. The testing of fuel pur-

chased by many branches of the Government is carried on by the Bureau, as the volume of this work makes it possible to carry it on in this way much more cheaply than through the employment of private agencies. For example during nine months of the fiscal year ending June 30, 1920, over 2900 samples involving roughly 38,000 determinations were tested.

As an illustration of work of the Bureau falling in the second group in class A may be mentioned improvements in health and safety conditions in quarries, mines, and metallurgical plants. This subject is a broad one including the work of the mine-rescue cars and stations in training miners in first aid and mine-rescue methods, the testing of explosives and equipment for use underground, the study of vocational diseases among miners, smelter men, etc., the study of mine sanitation, ventilation, and of a considerable number of problems related to safety devices and methods of safe operation underground. In the majority of these problems mining companies have a specific interest. In the nature of the case, however, the solution of these problems involves a study of conditions at many different points. Such a study can rarely be undertaken by any private or consulting engineer.

A number of activities of the Bureau fall in class B. Before citing any specific examples under this heading it may be well to mention briefly certain fundamental requirements which govern the choice of problems for investigation by the Bureau. In the first place the problem must be a real one, involving in its solution something more than mere routine work or the application of well known principles in a field where they have already been applied. In other words it is our aim to take up questions which involve real laboratory or field research and which are beyond the range of the ordinary consulting engineer or commercial laboratory. As a further general requirement a suitable problem should be one common to a branch of the mineral industry or to some mining district. A problem peculiar to a single mine or metallurgical plant, unless presenting some unique feature which might prove of general importance is not ordinarily considered within our field.

Recently the Bureau has carried on quite a little work in co-operation with private companies or individuals. There are two main reasons why this plan of co-operative investigation has been adopted. (1) The financial and other assistance furnished by the co-operative agency make it possible for the Bureau to do more work than would be possible under government appropriations alone. (2) Co-operation on the part of private company or individual in an investigation implies an active interest in the results of the work, and if the investigation turns out successfully, the results can at once be applied in a practical way, thereby leading to more rapid development and to an earlier realization of benefit than would be likely to occur if the investigation had been conducted independently by the Bureau.

There are two ways in which this co-operation is carried out. By one method the Bureau assumes full responsibility for the work, although the major part of the

expense is usually borne by the co-operating agency. Work of this sort is undertaken under a formal agreement in which it is provided that all information and data secured shall be available to the Bureau for publication and that any patents arising from the work shall be taken out in this country for the benefit of the general public.

Under the second form of co-operation the Bureau assumes no responsibility for the work, but merely places certain of its facilities at the disposal of a private individual or company with the understanding that the results of all work performed with facilities of the Bureau shall be available to the Bureau.

Generally speaking only subjects which fulfill the general requirements mentioned above will be taken up in a co-operative investigation. The same fundamental purpose applies to co-operative work as to strictly Bureau investigations, namely, the procuring of information which will be of value to the mineral industry.

It is in connection with these co-operative investigations that Bureau work approaches most closely the field of the private company or engineer. In some cases the initiative has come from the Bureau, but more frequently co-operative work has been taken up at the request of an operating company or engineer.

An illustration of a co-operative investigation, the study of the calcination of magnesite to be used in the manufacture of stucco, flooring, etc., may be mentioned. This work is being carried on at the Berkeley station jointly with the Northwest Magnesite Co., which is bearing practically the entire expense of the investigation. A number of other companies engaged in the same industry are also co-operating to the extent of furnishing materials and information, and it is agreed that information in regard to the progress of the work is available to any of these companies at any time.

The advantage from the standpoint of the company lies in securing the use of the laboratory facilities of the Berkeley station and a certain amount of scientific and technical assistance from the staff. From the standpoint of the public, the outcome of this work will be the same as though it were being carried on exclusively with government funds. The assistance of the Northwest Magnesite Co. makes it possible, however, to get on with the work more rapidly than would otherwise be possible.

MANGANESE ORE accounted for 87% of the total quantity of ores exported from India during the fiscal year 1918-'19. The quantity shipped decreased by 11% to 385,400 tons: 77% of the total exports went to the United Kingdom, and the remainder to France, Japan, the United States, Belgium, and Italy. Nearly 10,900 tons of ferro-manganese was exported from Bengal in the year under review. Wolfram ore was shipped entirely to the United Kingdom. The total quantity exported was 4870 tons, of which 4799 tons was from Burma and 71 tons from Bengal. The shipments of chrome-iron ore were 39,400 tons, as against a total of approximately 15,000 tons in 1917-'18.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

CALIFORNIA

FULLERS EARTH TO BE MINED BY ASSOCIATED OIL CO.

SHOSHONE.—The Associated Oil Co. is preparing to ship several hundred tons of fullers earth monthly from one deposit bought from R. J. Fairbanks, and from another leased from the Tonopah & Tidewater Railroad Co., the latter to be paid on a basis of \$1 per ton royalty. A. B. Peckham, the engineer in charge, is now in San Francisco conferring with officials of the Associated on the method to be used in mining the material. The beds vary greatly in thickness, but the average appears to be six feet. Mr. Peckham says steam-shovels may be used in removing the overburden and in mining the fullers earth, which will be shipped to Martinez, California, for use in refining lubricating oil. The Standard Oil Co., which secures fullers earth at Ash Meadows, has engineers at Shoshone, but it is not known that this company has bought claims. Mr. Peckham says indications are that the surrounding region contains many useful minerals that have been neglected because prospectors lack knowledge of them. He says the entrance of the Associated into the district caused a rush for claims containing 'soap', as the fullers earth is called at Shoshone, and that everything white was brought to him for examination. The Tecopa Consolidated is shipping 1200 tons of silver-lead ore monthly and is treating 100 tons monthly in an experimental concentrator. The mine is worked through a tunnel cutting the vein at a depth of 1000 ft. The Tecopa company was organized by John T. Overbury, who is now developing the nearby Paddy Pride, a promising prospect. In 1907, Overbury sold control to Nelson Z. Graves of Philadelphia, who built a 17-mile railroad to the mine and started development on a large scale. The manager is L. V. Marshall, who built and now owns the Needles smelter. The Tecopa has been the largest silver-lead producer in California for the last three years. Two tunnels have been driven in the Paddy Pride, the first cutting the vein at a depth of 180 ft. The vein in this tunnel is 10 to 12 ft. wide and two carloads of silver-lead ore have been shipped that gave net returns of \$1270 and \$1400. There is exposed a 1½-ft. width of ore assaying \$138. The second tunnel cut the vein at a depth of 500 ft. and it is being continued to the hanging wall of the vein, on which the ore was found in the upper tunnel. The Silver Rule and Blackwater have been sold by John Chambers to J. J. Jarmuth of New York for \$200,000, and the new owner plans to drive a 1000-ft. tunnel. Tonopah men have organized the

Death Valley Talc Refining & Manufacturing Co. to develop a huge deposit of talc three miles from the Paddy Pride. Tests have shown the material to be of marketable grade and the success of the company depends on what it will cost to haul the product to the railroad. Men who know the situation of the claims disagree as to whether this can be done.

COLORADO

PORTLAND COMPANY IS SINKING MAIN SHAFT.

CRIPPLE CREEK.—Deep development has been undertaken by the Portland Gold Mining Co., and sinking is now in progress with two shifts at the main shaft on Battle mountain. The shaft, now 2300 ft. deep, is to be sunk an additional 500 ft. and with powerful electric pumps in operation at the Roosevelt Tunnel level, no trouble is anticipated from water. Ore worth about \$1,000,000 has been mined from shoots developed between the 20th and 21st levels and the richest ore in the history of the mine is now coming from the 23rd level. It is estimated that production from between the 21st and present bottom level will reach \$2,500,000 in value. In addition to this rich ore, the ore in old stopes near the Portland No. 1 shaft on the south end of the property, is being hauled through the 7th level of the Independence, and 600 tons daily are delivered at the Independence mill. This ore will mill about \$3 per ton.

The Ocean Wave Mining Co., that is leasing the Ocean Wave, adjacent to the Portland on the south-west, has resumed production and a car of ore, estimated at 2 oz. per ton, was shipped to the Golden Cycle mill at Colorado Springs recently. The Isabella Mines Co., having failed to secure satisfactory bids for sinking the Empire State shaft, is doing the work on company-account. Lessees on the property continue production.

LEADVILLE.—An orebody opened in the Gertrude in Colorado gulch last fall is again being developed and ore assaying as high as 252 oz. silver, 41% lead, and 2½ oz. gold is coming to surface. Lessees on the property also hold leases on adjacent claims and are extending their work to hold their leases. South of the Gertrude, work has been resumed on the Golden Curry by lessees. The Tiger has been leased and lease-options are reported on the Venture; the Bartlett, Virginius, and Dinero tunnels are under operation by lessees. The Ready Cash tunnel is to be extended by the National Development Co., a Chicago corporation, and the bore is planned to cut the Cora May, Big Chicago, and the Aurora No. 1 and 2

at depth, and explore the veins and dikes traversing this territory. The same company is also operating the St. Kevin of the Parker group held under bond and lease. Work is also in progress on the Collins and Clarke groups in the Red Mountain section and on the Ruby, an old, but rich, producer. Other prospects are active and in fact more properties are being prospected than for many seasons past.

BRECKENRIDGE.—An electric hoist and compressor is being installed at the Deep shaft on Shock hill by the Deep Shaft Mining Co., recently organized. This shaft, the deepest in the district except the Brooks-Snyder, has reached 700 ft. The property, on account of litigation, has been inactive for 15 years. The power-line of the Colorado Power Co. has been extended to the property. Lessees on the Barger are sinking a new shaft and the owner H. K. Barger, who recently returned from California, is also sinking a shaft west of previous development. Bulkeley Wells, who recently became interested in the Iron Mask, is sinking a deep shaft near the portal of the Iron Mask tunnel and further development is planned.

TELLURIDE.—All machinery for the mill of the Valley View Leasing Co. has been delivered at the San Bernardo mine, the tramway is ready, and, with large tonnage of ore blocked out in the mine, steady production will be made as soon as the mill is completed. A recent assay-test has shown higher gold content in the ore now mined. The plant will start on or about July 10. The Bay State, active 20 years ago, is under examination and it is thought the low-grade silver-lead ore may now be mined at a profit. The Tomboy and Smuggler mills are operating steadily and shipments of concentrate are going forward.

SILVERTON.—The Gold King mill is operating steadily and turning out two cars of concentrate daily. W. Z. Kinney, manager, has returned from Denver, where the contract for purchase of the Gladstone-Silverton railroad was signed. The mine-output shortly will be increased when transportation facilities are furnished. The West vein, reported 75 ft. wide, is to be explored by a drift at the 700-ft. level, a contract having been awarded local miners by the Pride of the West Mining Co. for 800 ft. of work. The property, a rich producer of the early days, is expected to 'comeback'.

MICHIGAN

STATISTICS FOR MAY.

HFUGHTON.—Arcadian Consolidated has entered good-looking lode material on the 500-ft. level of the New Baltic shaft. The formation is identical in general physical characteristics with the lode uncovered on the 400-ft. level of the same shaft at the time operations were suspended during the War. When work was resumed this spring the shaft was sunk to the 500-ft. level. Drifting has started both north and south, but at this writing has not progressed any great distance. The shaft itself is in the hanging wall, so that there is a distance of 20 ft. to reach the strike from the shaft. The formation

is small mass copper. The width of the lode is not yet determined, but there is developed a length of at least 100 ft. The skip-rails have been laid, the timbering completed, and further openings will be made at once. In connection with the present exploration at the New Baltic shaft, it is significant that this shaft is 4000 ft. from the old Arcadian workings, and that the territory between has good possibilities as demonstrated by diamond-drills.

Victoria will become involved in litigation with Gogebic county, if present threats of officials are followed by action. The Victoria mine is situated in Ontonagon county, but the source of supply and outlet of water for its hydraulic compressor is Lake Gogebic. Gogebic county and several residents own land on the shores of Lake Gogebic. When the mining company first began to use the lake-water the level of the lake rose six inches. Recently it has risen six inches in two weeks. The property owners claim that it will rise 60 in. more. They assert that this rise in the water is damaging their property. In recent years the Victoria company has acquired considerable property on the lake shore, but not all of it. The supervisors of Gogebic county are holding a special session this week to determine upon legal action against the company.

The tabulated statement of the output for May 1920 is presented below. Seneca assumes its position among the permanent producers, and all of the larger producers show a decline in refined copper, due to the continued departure of laborers.

	'Rock' tons	Copper content		Production of refined copper	
		May lb.	April lb.	May lb.	April lb.
Ahmeek	72,000	22.95	26.36	1,652,900	1,700,500
Allouez	21,000	17.48	18	367,100	373,700
Baltic	15,000	36	35	540,000	619,000
Calumet & Hecla.....	196,831	25	25	4,920,786	5,320,063
Centennial	4,950	13.1	13.4	65,100	90,700
Champion	22,000	45	41	990,000	1,041,400
Isle Royale	44,800	19	18	851,200	1,083,700
Michigan	5,773	24	23.45	138,552	116,350
Mohawk	29,302	29	29.25	849,758	1,071,553
Oscuela Con.	44,050	16.7	16.1	739,500	716,200
Quincy	62,000	21	20	1,302,000	1,480,000
Seneca	5,611	30	30	168,330	107,070
Trimountain	8,900	32	32	284,800	374,400
Victoria	5,000	17	17	85,000	84,000
Wolverine	18,879	16.18	17.26	305,603	346,428
White Pine	8,791	21	20	184,625	179,713

MONTANA

NEW WAGE SCALE FOR NEIHART.

BUTTE.—The Tuolumne Mining Co. reports rich silver ore on the 500-ft. level near its Main Range shaft. The discovery is on the Spread Delight vein, it is five feet wide and gives an average assay of 30 to 40 oz. per ton. Specimens taken from this ore run as high as 1100 oz. per ton. The Davis-Daly plans further sinking of its Hibernia shaft. The adjoining Nettie mine is said to have uncovered high-grade silver ore below the present workings of the Hibernia, where the lowest are at 400 feet.

HELENA.—The Lump Gulch mines continue active production and development work. The Little Nell is a consistent shipper of high-grade silver ore, the Free Coinage is making good progress in its sinking operations, while

tunneling and drilling continue at the Muskegon and Mariner mines. Development work is in progress at the Sunset and Baby Helena mines. Operations have been resumed at the King Solomon group.

NEIHART.—The Cascade Silver Mines & Mills, the Neihart Consolidated Silver Mines Co., Flohart Silver Mines Co., and the London company have posted the following notice: "The mine owners and operators of the Neihart mining district will pay the following daily scale of wages: miners \$5, teamsters \$5, topmen \$5, blacksmiths \$6, blacksmith's helpers \$5.50, carpenters \$5.50, engineers (first motion) \$6, engineers (gear) \$5.50, pipemen \$5, station tenders \$5.50. Eight hours constitute a day's work. The I. W. W., O. B. U., and the Neihart Metal Mine Workers Union will not be recognized." The Neihart Silver Mines Co. has entered into a partial agreement with the union covering several points. A daily

GREAT FALLS.—Control of the Whippoorwill Mining Co. has been secured by F. Wright from Charles Wilkes of New York. The Silver Dyke properties at Carpenter creek are being opened. These properties were recently purchased from Heidenseck & Erickson, and are now under option to a syndicate of New York and Boston capitalists.

NEVADA

UNITED COMSTOCK.—RUBY HILL DEVELOPMENT CO.

CACTUS.—Drifts are being driven on the 265-ft. level of the Cactus Nevada and ore assaying 12 to 15 oz. is being opened. The vein is cut by numerous faults that make it difficult to follow, but it is much less broken than on the upper level. The cross-cut on this level, which was being driven beyond the main vein to the 'south' vein, has been discontinued 100 ft. from the

THE DOROTHY SILVER MINE AT WHITEHALL, MONTANA

wage scale of \$5.50 is being paid as before the strike. The present silver market has served to make the position of the companies a little stronger, while the strikers have been weakened considerably. Many of the single men have left the district since the strike was called.

CUT BANK.—The Black Chief mine has been taken over by local men. Operations on a large scale are planned as soon as a company is organized. Copper is the chief metal, with uranium an important secondary consideration.

CORBIN.—L. S. Roper has leased the property of the Alta-Montana Mining Co. from Costin and Merritt. Cross-cuts will be continued on the 13th level. These cross-cuts are entering the hanging wall of the old Alta vein.

COOKE CITY.—The Republic Mining Co. is shipping machinery for use at its Mohawk property. The equipment includes compressors, engine, and drills. Shipment of ore will be started at once. 2000 ore-sacks to sack the ore mined during the winter have also arrived.

shaft because of the extreme hardness of the rock. Ore assaying 75 to 100 oz. is being broken on the 100-ft. level. This is being shipped.

ARROWHEAD.—The west drift on the 100-ft. level of the Arrowhead has been advanced 100 ft. from the shaft and for 50 ft. it has been in ore $1\frac{1}{2}$ to 3 ft. wide and assaying \$125 to \$320. The existence of this ore has been proved 25 ft. below the 100-ft. level in a drift driven from a raise from the bottom level and the grade of ore at this point is similar to that on the 100-ft. level. The shaft is over 250 ft. deep and cross-cutting to the vein will soon be started.

DIVIDE.—The Victory has started shipping to the McNamara mill at Tonopah at a rate of 400 tons per month, but a statement of the value of the ore cannot be secured. The ore, coming from a depth of 350 ft., is reached through a winze from the 200-ft. level, and it is now planned to resume sinking the shaft.

VIRGINIA CITY.—The United Comstock has completed repairs to the Belcher surface plant and repairing of the

shaft has been started. Two shifts of miners are employed in sinking the Imperial shaft from the 400 to the 700-ft. level, and in the other mines of the company work preliminary to starting the haulage-tunnel is under way. The cyanide mill, to be built at a cost of \$1,000,000, will have a crushing and grinding capacity of 2500 tons daily, but the other equipment will at first have a capacity of only 1000 tons, which can be increased to handle the output of the entire crushing and grinding-plants as the tonnage is gradually raised to the maximum. The mill will have a gyratory, or Symons disc crushers, ball and tube-mills, Dorr agitators, slime-tables, and precipitation by zinc-dust. It is estimated that the treatment cost will be \$1 to \$1.25 per ton. The mining cost is estimated at \$1.50 per ton.

EUREKA.—Eight hundred tons of ore giving a net return of more than \$50 per ton has been shipped from a recently found orebody north of the main Dunderberg workings on the 400-ft. level of the Eureka Croesus. A winze has been started to prospect this shoot and several others in the immediate vicinity, and it is planned to reach a depth of 300 ft. below the level. This ore is in territory heretofore unexplored, as the early-day work at this depth in the Dunderberg was done in the south vein. The ore is 8 ft. wide in places and most of the value is in gold. Ore containing 30% copper carbonate has been found at a depth of 700 ft. in the Atlas claim. This ore also assays high in gold and silver. The Prospect Mountain tunnel of the Eureka King is 3200 ft. long and the Eureka tunnel is 2100 ft. long. These tunnels are being driven from opposite sides of Prospect mountain. The Eureka tunnel reaches a maximum depth of 800 ft. and the greatest depth reached by the Prospect Mountain is 1300 ft. The latter is now nearing an important vein in the limestone. Cutting of a pump-station and sump has been started on the 900-ft. level of the Locan shaft of the Ruby Hill Development Co. and unwatering of the shaft to the bottom, at 1200 ft., is to be started in a few days. Shipments are being made from the 900-ft. level. The two 75-hp. semi-diesel engines of the Eureka Holly, one for the hoist and the other for the compressor, are now working, and other important improvements have been completed. It is planned to develop the two main orebodies on a large scale, make connection with the Bullwhacker, where there is a good tonnage of shipping ore broken, and sink the Holly shaft from the present depth of 400 to 700 ft. It is reported that an experimental ore-treatment plant is to be built soon.

UTAH

PARK CITY AND EUREKA ORE-SHIPMENTS ARE CURTAILED.

OPHIR.—Conditions at the property of the Ophir Silver Mines Co., which recently resumed development work, are most promising, according to Sol Snider, superintendent. An average sampling of a rich streak in the upper claims assayed 173 oz. silver, 5.3% lead, and 7.69% copper. All of the seven main fissures of the district, from which millions of dollars worth of ore has

been produced, should cross the property. The company has expended \$30,000 in development work, and Snider states that shipping ore of high grade can be developed within ninety days. On the strike of the Buckhorn fissure, which crosses the company's upper claims, and is some 40 ft. wide, with a length of more than 1800 ft., samples have been taken that run from 100 to 1000 oz. silver per ton, besides containing both lead and copper. In the lower working-tunnel, which is now in some 700 ft., a cross-cut has been discovered 75 ft. from the portal and 85 ft. long, which had been run by previous owners in the early days. This cut follows a vein which at its face widened to more than a foot and was strongly mineralized. The company has a force at work in the lower tunnel, another in the upper workings, and a road-building crew.

PARK CITY.—An embargo by the Murray smelter of the A. S. & R. Co. held back shipments from local mines during the week ended June 19 and the preceding week. The embargo is a temporary one, due to labor conditions, which it is believed have now been relieved. The Silver King Coalition was unable to move ore during the week. Shipments totaled 1309 tons, of which the Judge M. & S. shipped 652 tons, the Ontario 501, and the Daly-West 73. The Judge smelter shipped 83 tons of premium spelter during the week.

L. R. Perry, president of the Iowa Copper Co., spent several days here recently. He stated that for more than 15 ft. the face of the cross-cut on the 200-ft. level has been in pyrite, and the expectation is that it will lead to a body of ore. Mr. Perry leased the Mount Masonic property, north of this camp, to Harry Barnicott, who, it is reported, will commence operations in the near future.

EUREKA.—Between the embargo still in effect by the American Smelting & Refining Co., and the slump in price of silver, local mines are producing only the minimum amount of ore necessary to keep their organizations intact, with the result that shipments from the district for the week ended June 19 totaled 122 cars, as compared with 143 cars for the preceding week. The Chief Consolidated shipped 36 cars; Tintic Standard, 25; Dragon, 19; Iron King, 8; Mammoth, 6; Iron Blossom, 6; Eagle & Blue Bell, 5; Victoria, 4; Grand Central, 4; Cornucopia, 3; Gemini, 3; Centennial-Eureka, 2; and Colorado, 1. The Tintic Consolidated Mining Co. in the North Tintic district is making preparations to commence work, according to George Nicholes, manager, who has been at the property making the necessary preparations. On account of the scarcity of labor at the present time, it may be late in the summer before development of the ground will be undertaken. A water-line is now being laid to the property. This property adjoins the Lehi-Tintic mine on the north.

The development of the Empire Mines ground through what is known as the 'Lower Mammoth' shaft has been stopped temporarily, according to officials of the Knight interests. This company owns an exceptionally large tract of mineral land in the central part of the district, and during the last few years there has been a consider-

able amount of development, most of it through the Lower Mammoth shaft. Jesse Knight has always had confidence in the Empire Mines, and it is with reluctance that he finally decided that it would be necessary for the present to suspend operations.

Operations by the Dragon Consolidated Mining Co. were suspended on June 20. This action was decided upon by the directors at a meeting held shortly before that date at Provo. There is a market for the iron ore, but there is only a small amount of profit under existing conditions and it is deemed best to hold the ore until such time as it can be made to yield a better revenue. While definite figures are not available, it is generally understood that the iron ore from the Dragon property has been bringing the company about \$3.50 per ton, from

BRITISH COLUMBIA

ROAD TO BE BUILT BEYOND PREMIER MINE.

STEWART.—Claims have been located on Fish creek, six miles above Hyder, over which Henry Benson, a resident of Victoria, B. C., and his sons are enthusiastic. They have a good vein and samples taken at the outcrop give returns of \$120 per ton in gold, silver, and lead. No trace of zinc is shown. The Bensons have organized a syndicate in Victoria and Vancouver and propose doing development during the summer.

The official announcement that the government of British Columbia plans the building of a road from the Premier mine, to which point there already is a fair road from tidewater, to Joker Flats has been received by

CHIEF CONSOLIDATED MINE AT EUREKA, UTAH

which has to be deducted the cost of mining and freight to Silver City, but not to the smelter. All of the product has been going to the United States smelter at Midvale and to the plants of the American Smelting & Refining Company.

ALTA.—At the Emma property, two teams are hauling ore from the mine-bins to the railroad siding at the Columbus Rexall property. Approximately 1000 tons of ore was accumulated. A new electric air-compressor is being installed at the property, which will be ample for the present needs of the mine. Work on the lower levels has been stopped for the present because of the heavy flow of water, which is about three times the normal quantity. Ore averaging from \$85 to \$90 per ton has been followed continuously for a distance of 127 ft. on the 500-ft. level of the Woodlawn mine, according to W. N. Lawrence, general manager. A shoot of ore 18 ft. long and $2\frac{1}{2}$ ft. wide, one of the objectives of the drift, has been cut.

mining men with satisfaction. Among the enterprises affected are the Big Missouri, on which work has been in progress for more than a year, and on which it is intended to do some 12,000 ft. of diamond-drilling; Mineral Hill, on which work has been done for two years; the Hercules, which is to be developed this summer; the Silver Tip and Silver Crest, being opened up by Vancouver interests; and the holdings of the Algonian Development Co. The latter company controls through a subsidiary concern, known as the Northern Light Consolidated, a group of claims situated adjacent to the Premier and diamond-drilling thereon is planned for this summer. The same company has the Spider group under option. This property is situated on the west side of Long lake and is equipped with an air-compressor and other machinery.

SHEEP CREEK.—A new concentrating mill, having a capacity of 50 tons per day, has been completed at the Emerald mine by the Iron Mountain, Ltd. This mine has

been one of the steady producers of this section of the Province. During 1917 the mine-run averaged: lead, 27% ; zinc, 5 to 6% ; and silver, $1\frac{1}{2}$ oz. As originally designed the mill was to have a capacity of 30 tons but the addition of an extra set of rolls for the crushing and some alterations in the process, principally in the direction of decreasing the proportion of product sent through the ball-mill, makes it possible to run through 50 tons, while the crushing capacity is 100 tons. The Nugget Mines, Ltd., has its property on a steady producing basis; the Mother Lode mill, remodeled and extended, is in operation. It is giving entire satisfaction. The ore is being taken care of as quickly as it can be brought to the surface.

NELSON.—The annual meeting of the California Mining Co. was held recently at Nelson when it was reported that good progress was being made in the development work under way on the California mine as well as on the installation of new machinery in the Athabasca mill, which is being put in shape for the treatment of the ore. Officers were elected as follows: John R. Cassin, Spokane, president; J. B. Schieger, of La Crosse, Wisconsin, vice-president; W. R. Orndorff, Spokane, secretary-treasurer; John Fraser, Nelson, auditor; W. H. Turner, Nelson, mine superintendent.

VANCOUVER.—The town of Phoenix will soon be no more. It is gradually being dismantled. The Granby Consolidated Mining & Smelting Co. has a crew of 30 or 40 men dismantling its plant and shipping it to Grand Forks and elsewhere; 20 or 30 cars having been forwarded already. This work will not be finished before August when the Canadian Pacific will remove its steel. The depot now is being taken away. The Great Northern has been busy for the past month removing equipment. Several buildings in the town also are being taken elsewhere.

ONTARIO

HOLLINGER COMPANY ISSUES INTERIM REPORT.

TORONTO.—The stamp-tax on the transfer of shares of stock, originally fixed at two cents per share irrespective of the par value, has been modified and fixed at two cents on each \$100 face-value of the stock transferred. It is stated that the change was made because there are so many low-priced mining stocks, on which the tax as at first proposed would have represented a large percentage of their value.

PORCUPINE.—An interim report of an encouraging character has been issued by the Hollister Consolidated covering the period from January 1 to June 2, during which the total income was \$2,879,706, compared with \$2,822,858 for the corresponding period of last year. The expenditure was \$1,448,020, compared with \$1,507,060, and the net profit \$1,431,685, as against \$1,315,798. The average tonnage treated per day showed an increase, being 4056 tons, as compared with 3907. At the annual meeting of the Dome Mines company, held on June 18, it was announced that dividend-payments would be continued at the present rate and that instead of increasing dividend disbursements, surplus earnings would be de-

voted to the repayment of capital, as the \$1,000,000 possessed by the company in cash and bonds gives it all the working capital necessary. Reports as to the closing down of the mine were referred to by C. D. Keading, general manager, who stated that unless the miners quit work or demanded higher wages than they were now receiving there was no intention of shutting down.

KIRKLAND LAKE.—From present indications five mines in the Kirkland Lake district will be producing gold before the end of the year. At present the Lake Shore, Kirkland Lake, and Teck-Hughes are treating an aggregate of nearly 300 tons daily, and producing at the rate of about \$115,000 per month. With the Tough-Oakes mill again in operation, and the completion of the Wright-Hargreaves mill, the daily tonnage treated should approximate 600 tons with a monthly output of at least \$200,000. The King Kirkland Gold Mines, with an authorized capital of \$2,500,000, has been organized for the development of a group of seven claims having an area of 309 acres in the central part of Lebel township. Operations have been begun on a vein which has been uncovered for 150 ft. and contains visible gold.

SKEAD TOWNSHIP.—This district is attracting increased attention and development is being carried on by a number of companies. The Wisconsin-Skead has installed a mining plant and has done considerable underground work at the 112-ft. level, where some good veins have been tapped by cross-cutting. Diamond-drilling has indicated a series of veins with good gold content. The shaft will be put down to the 300-ft. level. Surface work is being done on the Crawford-Skead, lying west of the Wisconsin. The Fidelity, which owns a group of 10 claims on St. Anthony lake, plans a diamond-drilling program. Many claims were taken up in this area as early as 1906, but the high cost of development and the difficulty of getting in supplies discouraged operations. Now that conditions are more favorable, work may be resumed on many of these properties.

COBALT.—With United States currency at a premium of around 15% in Canada, the producers of silver in Cobalt are able to market their metal in New York and receive the advantage of payment in American funds. The added revenue from this source alone is about \$150,000 monthly. Cobalt mining companies have been approached on the subject of lending their support to two or more oil-prospecting syndicates which propose to carry on exploration work along the Abitibi river at a point less than 150 miles north from Cochrane where members of the Geological Survey announce the discovery of shale in which crude oil is contained. Activity in the South Lorrain silver-area is increasing. The Associated Gold Mines of Western Australia is operating the Keeley mine, and reports having opened a moderate tonnage of medium-grade ore in the lower workings. The company has acquired an option on the adjoining Beaver Lake property and is stated to have found ore extending across the boundary from the Keeley at a depth of about 230 ft. The Haileybury Frontier mine in South Lorrain is also being re-opened.

SALE OF SILVER UNDER THE PITTMAN ACT

For the benefit of the producers of silver ore who sell their product to smelters, samplers, custom concentrators or cyanide plants, or to refiners, the Director of the Mint has revised, with the approval of the Comptroller of the Treasury, the affidavits required in connection with the sale of silver at the rate of \$1 per ounce as provided in the Pittman Act. A careful examination of these affidavits will make the conditions of such sales clear. The original producer should furnish the 'Miner's Supporting Affidavit' with each shipment of silver-bearing ore in order that he may get the immediate benefit of the fixed price. In order that the vendor, who is usually a refiner, may realize on silver for which he paid \$1 or more per ounce, but which he has had in process for some months, provision is made for ore received at reduction-works since January 17, 1920. The form of the affidavits follows:

AFFIDAVIT BY VENDOR IN CONNECTION WITH PURCHASE OF SILVER UNDER PITTMAN ACT

State of } ss.
County of }

In order to make a sale of silver to the Director of the Mint in accordance with the provisions of the Pittman Act approved April 23, 1918, the undersigned hereby represents and certifies under oath that he is the of
(Title of office)

....., owner of certain silver to the amount
(Name of vendor)

of fine ounces more or less, forwarded to the United States Mint at on the day of 1920, and delivered for sale to the Director of the Mint under the provisions of said Act for account of said vendor; that said silver is the product of mines situated in the United States and of reduction-works so located, being either (1) wholly without admixture of the product of foreign mines or reduction-works, or (2) part of a mixture of foreign silver and domestic silver delivered to domestic reduction-works since January 17, 1920, and within the proportionate part of such mixed product which represents the product of mines located within the United States and of reduction-works so located, delivered by such mines to such reduction-works since January 17, 1920, after taking into account sales heretofore made to the Director of the Mint under said Act; and that the vendor will forthwith file with the Superintendent of said Mint such statements and exhibits from its books of account and also such supporting affidavits and sworn statements of exhibits by itself and by the miner, smelter, and refiner, as may be demanded by the Director of the Mint under said Act.

.....
(Signature of vendor or duly authorized officer)

Subscribed to and sworn to before me this day
....., 192...

.....
Notary Public.

MINER'S SUPPORTING AFFIDAVIT

State of } ss.
County of }

The undersigned, being duly sworn, deposes and says:
That he is the of
(Title of officer) (Name of mine owner)

owner of the mine, situated in the County of
(Name of mine)

....., State of; that the said
(Name of mine owner)

has sold and delivered to on the day of 1920, at its smelting plant known as the smelter, situated in the County of, State of, fine ounces of silver, which was produced at the said mine located as aforesaid and contained in certain parcels of ore as described in settlement or liquidation sheet No. of said, and that said silver was paid for at the rate of not less than \$1 per ounce, adjusted to the equivalent price of silver 999 fine and to the cost of delivery refinery to mint.

Subscribed and sworn to before me this day of 1920.

.....
Notary Public.

COLORADO

Denver.—The dates for the first-aid and mine-rescue contests which, in a way, will be international in their scope, in that miners of Canada and Mexico, as well as those of the United States, will be invited to participate, has been changed to September 9, 10, and 11. Contests were held at Pittsburgh last year and teams from Colorado, Montana, and Washington were represented. The meet is held under the auspices of the Bureau of Mines.

Mayday.—Lon Wigmore and associates have secured a lease on the Lucky Moon and have started a tunnel to cut a vein along a fault where some good ore was mined a few years ago.—It is reported that lessees have taken over the Mountain Lilly, situated above La Plata, and have begun work there. This property, it is said, has produced a small amount of ore, but has been idle for some time.—Thomas Welborn and Joe Clark are making an examination of the Tomahawk, with a view to taking a lease. They are also working the Idaho dump, and have shipped two cars of ore which assayed \$40 per ton.—Wm. Graflin has a force of men at work on the Copper Queen.

IDAHO

Twin Falls.—Arrangements are being made for the erection of a 100-ton mill at the Buhl-Jarbridge mine at Jarbridge. This announcement is made by J. C. Deemer, general manager of the property, who says the work will begin as soon as roads to the mine are in condition to use, which should be in about a fortnight. Power-drills, it is expected, will be in operation not later than September 1. Mr. Deemer states that the Windy vein, where it outcrops on top of the mountain, is only eight inches wide, while 640 ft. below the sur-

face, in the tunnel, this vein is 17 ft. wide, assaying \$12 per ton.

MINNESOTA

Duluth.—Further curtailment of mining work on the iron-ranges, due to shortage of coal as well as boats to take ore from the docks, is reported in many sections. Range-pits that increased the number of shovels at work recently have been again forced to reduce operations to a minimum. Shipping has been almost entirely discontinued and other work is being regulated by transportation facilities.

MISSOURI

Joplin.—A record week's output of zinc has been made by the Chanute Spelter Co. from its mine one mile west of Baxter Springs. In six working days of 24 hours each the output was 458 tons of zinc and 14 tons of lead. The next highest record in this district was made by the Skelton mine near Douthat, which produced in one week 438 tons of zinc. Production figures for the district are: blende, 18,462,880 lb., \$408,358; calamine, 459,660 lb., \$8050; lead, 2,009,730 lb., \$145,300; total value, \$561,708. Average value per ton, blende, \$44; calamine, \$35; lead, \$100. Twenty-four weeks: blende, 534,571,640 lb., \$13,550,487; calamine, 8,984,620 lb., \$170,039; lead, 90,478,000 lb., \$4,781,065; total value, \$18,501,613.

Beer, Sondheimer & Co., of New York, have brought suit in the Supreme Court against National Zinc Co., to recover \$873,342, alleged to be balance due plaintiffs for advances at different times to the Zinc company. It is alleged that demand for payment of balance alleged due was made June 1 and was refused.

UTAH

American Fork.—Operations at the Globe mine in American Fork canyon are being pushed steadily, according to John Cleghorn, manager. From four to six feet of progress per day is being made in the drift along a north-south fissure to its intersection with an important vein about 150 ft. ahead. At present the formation is well mineralized, with bunches of carbonate ore appearing at intervals.—W. S. Cool, of Salt Lake City, owner of the Sierra patented claims, has been here recently, arranging to start work on his property. These claims adjoin the Miller mine, a big producer in early days.

Vernal.—The Jeannette Copper Mining Co. will resume operation of its property in the Uinta basin about July 15, according to Wm. O'Neil. The mine has been idle since 1916. The property consists of 34 unpatented claims, situated about 35 miles south of Rock Springs, Wyoming, the nearest railroad point. Development consists of approximately 1000 ft. of tunnel and shaft-work. It is stated that some rich copper ore has been developed, which the company will start mining and shipping.

Santaquin.—The Union Chief Mining Co. will ship three cars of high-grade lead-silver ore from its mines, according to Alfred Larson, superintendent. The company has recently completed work on a road from the mine to the railway, a distance of three miles. Ore showings in the mine continue to improve, and a fair amount is being taken out from development work.

WASHINGTON

Northport.—An orebody on the line of the Gladstone and Electric Point mines, opened in the Gladstone to a depth of 50 ft., has been cut by the Electric Point in a cross-cut at a depth of 145 ft. At the new point it is on both sides of the line. It contains lead in carbonate and sulphide form. The Gladstone has opened six chimneys, four within recent weeks. The sixth has been followed by a shaft to a depth of 43 ft. and is said to contain carbonates and some sulphides. The last carload weighed more than 43 tons. The ore contained 78.4% lead and the gross value was \$4272, of which \$4 per ton was in silver.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

H. S. Denny is returning to London from Montreal.

S. E. Bretherton has gone to Seattle and Vancouver.

F. Le Roi Thurmond is at Santa Barbara, Chihuahua.

Fedor F. Foss, of New York, is at Rockville, Maryland.

Arthur Feust is with Hughes & Dies, at 42 New St., New York.

J. H. Forman, of Tonopah, Nevada, has moved to San Francisco.

J. B. Annear has moved from Panaca, Nevada, to Merced, California.

Philip Wiseman, of Los Angeles, is in New York, on his way to London.

William Compton has moved from Fairfield, Idaho, to Virginia City, Nevada.

Warren D. Smith is returning to the Philippines as Chief of the Division of Mines.

Conway G. Williams has changed his address from Ajo, Arizona, to Garfield, Utah.

Edwin E. Chase, of Denver, has gone to Wyoming to examine some copper mines.

Charles E. Prior Jr. is engineer with the Premier Gold Mining Co. in British Columbia.

G. O. Murray is still at Asanboni, India, being unable to go to London as he had intended.

M. J. Weller, superintendent of the Greenhorn mine in Shasta county, is in San Francisco.

R. C. Warriner, formerly general manager of the Crown Mines, on the Rand, is visiting California.

Alan M. Rodgers, of Washington, D. C., is now with the Moctezuma Copper Co., at Nacozari, Mexico.

Lewis A. Levensaler has opened offices as consulting mining engineer at 902 Hoge building, Seattle.

O. F. Brinton, general manager for the Western Utah Copper Co. at Gold Hill, Nevada, is in New York.

Clarence A. Wright, of the Salt Lake City station of the U. S. Bureau of Mines, has gone to Trentino, Italy.

Alfred Hunt has been appointed superintendent for the Angels Camp Deep Mining Co., at Angels, California.

Homer Guck, for the past 15 years editor of the 'Daily Mining Gazette' at Houghton, Michigan, has resigned.

Alan M. Bateman, professor of economic geology, at Yale University, has gone to British Columbia and Alaska on professional business.

L. T. Buell has taken a position with the Phelps Dodge Corporation at Douglas, Arizona, after having spent several years in South America.

Horatio C. Ray has resigned his position with the School of Mines, University of Pittsburgh, to become connected with the Keystone Consolidated Publishing Co., at Pittsburgh.

Glen D. Cook, mining engineer of Salt Lake City, who has been operating the Montezuma and Jersey mines in Pershing county, Nevada, has organized the Pershing County Mines Co.

H. Hardy Smith arrived in San Francisco on June 23 on the 'Tenyo Maru' from Korea on his way to New York, where he will remain three weeks. He will return to San Francisco before sailing for Australia.

R. Allison Purvis, of London, arrived on June 23 in San Francisco on the 'Tenyo Maru' from the East, having escaped from the Bolsheviks in Siberia, where he was imprisoned by them from January until April at Krasnoyarsk, Irkutsk. He will sail for London from New York on the 'Mobile' on July 10.

THE METAL MARKET

METAL PRICES

San Francisco, June 29

Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

June 28.—Copper is inactive but steady. Lead is dull but steady. Zinc is quiet and firm.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and with contents to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

FOREIGN EXCHANGE

Discussing the improvement in sterling exchange, the Anglo-South American Bank of London analyzes the situation as follows: "In case of countries whose currencies are at a discount as compared with ours, there has been a fairly general contraction in the premium on sterling the past month or so, this improvement being particularly marked in the German quotation. Premium on sterling as compared with marks has fallen since the end of January from 1686% to 69%, while in case of Paris the present premium in sterling of about 102% compares with 170% two months ago.

"This recovery in value of depreciated foreign currencies compared with sterling, however, has not had any adverse effect on the position of sterling as compared with markets in which British currency is at a discount. In New York, discount on sterling is now about 20%, against 31% in February, the extreme mark during the present year, and in most other markets in this group the experience has been the same. Presumably London, which previously was affected by its own indebtedness to New York, and indirectly by indebtedness of other countries for which it acted as intermediary in exchange transactions, is now benefiting not only from improvement in our own exports but from the better trade position being established by certain continental countries.

"How substantial has been the improvement in European trade position as against the United States the following figures show. During April value of United States shipments to Europe declined \$135,000,000 compared with April of last year, but imports from Europe increased \$68,000,000 and practically \$700,000,000 for 10 months to April 30. Figures of United States exports to this country showed substantial reduction, and corresponding imports, almost as substantial an increase, while in case of France, also, marked improvement is shown, value of French exports to United States for 10 months being \$145,000,000, against less than \$45,000,000 the preceding year, while during the same period French imports from United States declined just over \$200,000,000. It is true the balance of trade is still heavily in favor of America, but all evidence goes to show Europe has appreciated the need for lessening of consumption and increase in production, and is acting accordingly.

"In these circumstances, improvement in the European exchanges as compared with the dollar is only natural, but the position has also been affected by definite decision of the British and French governments to repay the \$500,000,000 Anglo-French loan at its due date in October next, by heavy gold shipments made to the States on this account, and also by large sales of government-owned wool, while another factor of more temporary character but of considerable importance is the definite postponement until 1922 of interest payments on our debt to the American government. This was disclosed by Austen Chamberlain in answering a House of Commons question on May 5, and incidentally he stated that approximately \$23,000,000 was included in the debt charge for the current financial year in respect of interest on debt raised outside the United Kingdom, but that the amount due from this country to the American government alone would, at par of exchange, amount to \$43,000,000 per annum."

MONEY AND EXCHANGE

Foreign quotations on June 29 are as follows:

Sterling, dollars:	Cable		Demand	
	cents	pence	cents	pence
France, cents:	Cable	8.40	Demand	8.43
Lire, cents:	Cable	6.01	Demand	6.01
Marks, cents	Cable	2.75	Demand	2.75

Eastern Metal Market

New York, June 23.

There is still an absence of demand for practically all the metals and prices of some have fallen.

Demand for copper is very light but prices are steady.

While buying of tin is light, values have been advancing and the market is fairly strong.

Lead has declined quite decidedly and there is no urgent demand.

The zinc market is still lifeless and prices are lower.

Antimony is a little easier.

IRON AND STEEL

Iron and steel producers are still traveling in a circle, bet-terment in car and fuel-supply being quickly followed by a return of old conditions, says 'The Iron Age'. This week the breaking out of fresh railroad strikes at Philadelphia and Baltimore has crippled several Eastern steel-plants, and em-bargoes against the affected districts have been put in force at Pittsburgh.

Fuel-shortage has driven some pig-iron producers to pay new high prices for coke and \$17 has been reached in the dizzy ascent of that market. Basic pig-iron also tends higher. On the other hand are easier prices in plates and shapes; but with little promise of better than 75 or 80% production for many weeks, no significant readjustment of finished steel prices is looked for.

The buying of steel cars by steel and coke companies goes on. In the past week such new inquiries involved 2700 cars and one car-works took orders for 1500.

The possibility of a sheet and tin-plate shut-down on June 30 has led to recent re-sales of sheet-bars, some bessemer bars having been offered at \$65 to \$70 and open-hearth bars at less than \$75, representing some easing-off.

A new development in the coke market is the inquiry com-ing from South American and European sources, including one for 10,000 tons per month for 18 months. Owing, how-ever, to the shortage in this country and to the high prices, it is not expected that exports will be heavy.

COPPER

There is no change in the general situation—at least not for the better. A fresh outbreak of 'outlaw' railroad strikes in the East is not an encouraging sign, particularly in the Baltimore territory where there are large refinery interests. It may be necessary to shut-down one or two refineries there should the matter grow worse. Demand is very light and prices as a result are largely nominal. Large producers continue to quote 19c., New York, for both Lake and electrolytic for early delivery and see no reason to change. Small pro-ducers and some outside interests are quoting as low as 18.25c., New York, for electrolytic for early delivery. The large interests are booked up well ahead but difficulties of various kinds are limiting output and shipments.

TIN

There has been a gradual advance in the quotation for spot Straits, New York, and it is believed that the low level was reached last week at 45.50c. Yesterday the quotation was nominal at 50c., New York. The higher trend is due largely to a strong London market. Yesterday spot Straits in London was quoted at £270 per ton. In the week on this side the market has been quiet on the surface but a fair record in sales has been made. These have been participated in largely by dealers though consumers have done a little buying. One large consumer inquired last week Thursday for 200 tons which is understood to have been closed. On Wednesday last week, on the New York Metal Exchange, sales of 225 tons were recorded as well as 50 tons on Tues-

day. Of the 225 tons on Wednesday, 200 tons was Straits tin for July shipment and future shipment from the East, all at 45 to 45.25c. There was a 25-ton lot of Chinese tin which was sold at 42.12½c., the sale being forced because of the failure to protect a margin, according to reports. Last Saturday there was an active demand for future shipment but there was a lack of sellers, not much business being done at bids of 47.75 to 48c. With London advancing, a buying-movement on this side is expected soon. Arrivals of the metal to date this month have been 2695 tons with 4430 tons reported as afloat.

LEAD

A dull market here for several weeks as well as the slump in London a week ago have been the causes of two sharp re-ductions in prices. Late last Tuesday, June 15, the Amer-ican Smelting & Refining Co. reduced its quotation ½c. to 8c., St. Louis, or 8.25c., New York, and then on the next day re-peated the operation, making the level 7.75c., St. Louis, or 8c., New York, for early delivery. The outside market, which had been above the Trust price for some time, met this and is now quoted at around 7.90c., St. Louis, or 8.15c., New York. The fear of imports of the metal is also alleged as a cause for these reductions. It is a fact that lead is not plentiful for spot delivery or for early shipment from the West, neither is there any urgent demand.

ZINC

Extreme dullness still characterizes this market. There is no extensive buying and the general basic conditions men-tioned last week still prevail. Values fell to lower levels late last week when 7.35c., St. Louis, for prime Western prevailed, but since then there has been an advance, due to a higher London market. Today prime Western is quoted at 7.45 to 7.50c., St. Louis, or 7.80 to 7.85c., New York. Pro-ducers are still inactive sellers and are only taking care of customers' immediate needs. Galvanizers are not active buyers, due to the uncertainty of the future.

ANTIMONY

The market is dull and inactive. The metal is quoted at 7.75c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Quotations are unchanged at 33c., New York, from the leading interest and 31.50c. from other sellers for whole-sale lots for early delivery.

ORES

Tungsten: There are no transactions recorded and the market is flat. The last quotation, which was nominal, was \$6.50 per unit for Chinese ore with other grades correspond-ingly higher. Until general business conditions improve no life to the market is likely.

Ferro-tungsten is unchanged and nominal at 85c. to \$1.15 per lb. of contained tungsten.

Molybdenum: This market is also dead with quotations nominal at 60 to 65c. per lb. of MoS₂ as the foreign quota-tion and 75c. as the local.

Manganese-Iron Alloys: There continues to be an absence of inquiry for both prompt and last-half delivery. Prices are firm at \$225 to \$250 for prompt and \$200 for last half. The only inquiries are about 300 tons for last half. Spiegeleisen is firm at \$75, furnace, but the market is quiet.

Kerosene export quotations in New York have declined twice since June 1. A drop on June 7 from 15c. to 14.25c. per gallon for standard water-white, in bulk, was followed by a second on June 12, from 14.25c. to 13.50c.

Book Reviews

Structural Drafting and the Design of Details. By Carlton Thomas Bishop. Pp. 338, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

This is a textbook for students and apprentices and a reference book for structural draftsmen. It is divided into three parts. Part I is introductory and gives a general discussion of the organization of a structural-steel company and of the manufacture and fabrication of structural steel. Part II is devoted to drafting-room practice. The discussion is complete, from the mechanical details of the use of tracing-cloth and ink-erasers to the laying out of beams, girders, and columns. Part III deals with the design of details in a similarly thorough manner. An appendix contains the usual data regarding properties of standard structural shapes as well as a number of other tables and diagrams useful in this class of work.

Manual for the Oil and Gas Industry. By Ralph Arnold, J. L. Darnell and others. Pp. 176. Ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

Whatever we may think of the various provisions of the internal revenue laws relating to corporation taxes, the fact remains that corporations must make returns under these laws. The present volume was originally issued as a bulletin of the Internal Revenue Bureau, and is designed to assist members of the accounting departments of companies producing oil in making the calculations necessary for preparing the proper tax return. The scope of the book is indicated by the titles of the various chapters, which are Amplification of the Law and Regulations, Estimate of Depreciation of Equipment, and Estimate of Recoverable Underground Reserves of Oil. While the book, as already noted, is primarily designed for those preparing Federal tax returns on behalf of oil companies, it will be useful to anyone interested in the valuation of oil properties.

Text-book of Inorganic Chemistry. Vol. IX. Part I. By J. Newton Friend. Pp. 366. Index. Charles Griffin & Co., London. For sale by 'Mining and Scientific Press'. Price, \$6.

The general plan of this series has been to devote one volume to each of the groups of elements according to the periodic classification. In this instance iron has been treated separately in Part II so that this particular book deals only with nickel, cobalt, and the palladium and platinum groups. For the research student, as the author points out, fuller details are necessary than can be included in a text-book of this scope. Accordingly copious references are given to the original memoir. While the past two decades have marked rapid strides in the development of the chemistry of the metals and their compounds, there is still a deal of uncharted territory yet to be explored. This work is new and is based upon the present state of our knowledge of inorganic chemistry. The book is of course designed for the use of the student and for that purpose it is well adapted. It appears to be comprehensive, clear, and well arranged.

Forge Practice and Heat-Treatment of Steel. By John Lord Bacon. Third edition. Pp. 407. Ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$1.75.

The author of this book was for some time instructor in forge practice at the Lewis Institute at Chicago, and the text is based on notes prepared for courses given there. In the third edition the subjects of hardening, tempering, and an-

nealing are treated at considerably greater length than in the previous editions. The first chapter is devoted to a general description of the blacksmith's forge and tools. Welding in the forge is next discussed, and then the making of all kinds of hand forgings, including the calculation of stock, and the methods of actually doing the work. Steam-hammer work is then considered, also the use of dies to produce duplicate parts. The remainder of the book is mainly devoted to tempering, hardening, annealing, and casehardening, and discusses both the equipment used and the methods of doing the work. The treatment is non-technical and practical throughout, theoretical discussion being eliminated as far as possible. It will be of value not only to the apprentice and mechanic but also to the engineer who either uses or has charge of the manufacture of forgings.

The Mines Handbook. By Walter Harvey Weed. Pp. 1976. W. H. Weed, New York. For sale by 'Mining and Scientific Press'. Price \$15.

The latest issue of this valuable publication is just to hand. It covers the years 1918, 1919, and the first quarter of 1920. Much of the information is brought down to April of the current year. The present volume contains 70 pages more than that issued in 1918, and the number of companies listed has increased by 1000, making the total 7400. It would be well if all the advertisements could be placed at the back of the volume; also the index. The geographical arrangement by countries, States, counties, and districts is advantageous. As usual, the volume contains a glossary and a brief description of the principal copper minerals. It is evident that there has been some difficulty in getting information concerning certain mining enterprises, but this is the usual experience of statisticians and compilers of industrial data. As this volume becomes a public institution, it ought to receive increasing support, not only by its sale but also by a greater willingness on the part of mining companies to assist the editors by giving them the needed information. The new districts, in Nevada and British Columbia, for example, are creditably complete. Consolidations, absorptions, and liquidations are carefully recorded. No less than 460 pages are devoted to mining companies in foreign countries, particularly those to which American energy and capital are being diverted. The collection of geologic and metallurgic data gives technical value to the volume. The various statistical tables have been brought up to date. This handbook is the successor to the one started by Horace J. Stevens in 1900. It is fortunate that a man so well informed as Mr. Walter Harvey Weed should have taken up the work when Stevens died. We are frank to say that we find the 'Mines Handbook' of great use to us in our editorial work, and we can surmise how useful therefore it must be to others requiring prompt information concerning the organization, personnel, and production of mining companies in various parts of this country and also abroad. It is extremely difficult to compile so large a mass of information without introducing errors, but the marvel is that there are so few. Without question, the 'Handbook' is performing a highly useful function, and we hope that Mr. Weed's enterprise will meet with public support.—T. A. R.

Engineering for Land Drainage. By Charles G. Elliott. Pp. 353. Ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

This is the third edition of a book which, appearing originally in 1902, has come to be regarded as a standard treatise on the subject. Comparing it with the second edition, we find several changes and additions, including a revision of the discussion of the hydraulics of flow in underdrains, new tables for computing the discharge of tile-drains, and additions to the discussion of drainage by pumps and of drainage of irrigated lands.

INFORMATION FURNISHED BY MANUFACTURERS

THE SELECTION AND TREATMENT OF TRANSMISSION BELTS

By E. J. Black

The right and wrong ways of lacing belts are shown in the accompanying illustrations. The top and bottom views show a belt which has been properly laced. The holes were punched evenly and the lacing was done smoothly, leaving no loose ends which might catch and injure the belt. The middle view shows a belt improperly laced. The holes were punched in some instances so close together that the lacings tore through. A belt laced like this cannot be expected to give the maximum amount of service. The following detailed instructions as to the proper way of lacing may well be studied.

(1) Cut the ends of the belt absolutely square. Do not depend upon your eye or use an ordinary ruler. If the end is slanted in the least degree all the pull will come on one

side of the belt and the consequences are likely to be disastrous. (2) Make the holes as small as practicable. Use an awl rather than a punch, wherever possible. (3) Leave a sufficient margin at the edge of the belt without holes so as not to impair its strength. In belts 2 to 6 in. wide, the holes should not be nearer to the edge than $\frac{1}{4}$ in., in belts 6 to 12 in. wide not nearer than $\frac{1}{2}$ in., and belts 12 to 18 in. wide not narrower than $\frac{3}{4}$ in. (4) Make two rows of holes, in parallel lines straight across the width of the belt, and stagger the holes, so that the strain comes upon different portions of the belt. (5) Be sure that the holes in the two ends to be joined match exactly. Otherwise there will be a 'jog' in the belt, and this is likely to result in tearing the belt lengthwise. (6) Use flexible lacing, being careful to have it proportionate to the size of the belt. A heavy lacing is likely to cause trouble. (7) In lacing the belt, make the pulley side as smooth as possible. Rough places and ends should be turned away from the pulley. (8) In using metal fasten-

ers select those which place the strain on the length-wise strands of the belt. The cross-wise strands are not as strong as those which run length-wise.

Besides improper lacing, there are many other abuses which shorten the life of belts. Shafting that is out of line may cause an undue strain upon the belt and make it run off the pulley. Oil may be allowed to drip upon the belt and ruin it. The belt may be applied with an initial tension so great as to produce an unnecessary strain. Many complaints regarding unsatisfactory belt performance can be traced to the fact that the wrong belt was used on the job. No matter how good a belt is or how good treatment it receives it

the width of the pulley face, or by changing the arrangement of a vertical belt so as to give a certain degree of slant.

The factors which are under the belt man's control are these: (1) The kind of belt to be used, such as rubber, leather, canvas, etc.; (2) the grade, whether cheap, medium, or high; and (3) the weight of the belt, such as 4 or 6-ply, single or double.

In determining the kind of belting to be used, the merits of rubber belting should receive full consideration. It is economical in first cost, extremely efficient in service, and frequently outlasts other constructions. On the other hand, in places where constant contact with oil is unavoidable, a rubber belt will not give good service. The constant use of shifters is also injurious to a rubber belt.

In deciding upon the right grade for a particular service, the points to be especially considered are the size of the pulleys, the presence of idlers or other unusual conditions, and the speed. Small pulleys, operated at high speed, necessitate a high-quality belt. The reason for this is the internal wear between the various plies of fabric, and even between the fibres in each ply, as the belt rounds the pulleys. A high-grade rubber friction is the best possible protection against this internal wear, because it protects each fibre with an elastic coating which remains uninjured and which indeed retains its life and elasticity longer when in use than when lying idle.

In this connection, it should not be forgotten that the value of a particular rubber friction cannot be determined merely by the test showing 'pounds pull'. If the plies were fastened together with glue, this test would show a very high-grade belt, but we all know that such a belt could not give service. The most valuable property of rubber friction is that intangible quality called 'life'. There is no known test for this but length of service. In specifying the proper ply for the installation, the determining factors are the size of the pulleys, width of the belt, speed, and the horse-power to be delivered. The belt itself should be at least one inch less in width than the face of the pulley.

'GUNITE' FOR FIRE-WALLS

Some months ago the architects of a large factory in the East decided to use as a 'fire-wall' a hollow wall with 'gunite' sides two inches thick, with an eight-inch air space between, and with the side walls connected with gunite studs at from 5 to 7-ft. intervals. The outer walls were reinforced and the studs had two $\frac{1}{4}$ -in. round rods as vertical reinforcement. This construction was refused. 'Fire-wall' in insurance parlance is distinguishable from 'fire stop', in that the latter means a wall that will act as a temporary retardant to prevent the spread of fire, while a 'fire-wall' is supposed to be a wall that will actually prevent the spread of fire from one portion of a building to another portion. Inasmuch as the only material which had ever been classified as a 'fire-wall' construction, and the only construction that had been used in this connection, had been a brick wall not less than 12 in. thick and increasing in thickness due to the height and character of the partition, the architect was faced with the quandary of getting a decision in favor of the gunite construction or of delaying the erection of the plant for an indefinite period, on account of the scarcity of both brick and brick-masons. The insurance company was sufficiently interested to request that the Underwriters' laboratories make arrangements to test samples to be made in conformity with the scheme proposed. The final test was completed on June 3 and 4.

The samples tested were reproductions of a section of wall, the studs being spaced with 7-ft. centres and side walls extending about 18 in. beyond each stud to their intersection with the brick frame. The walls were 'shot' about April 20, and had cured since that time. To avoid excessive dampness, they had been surrounded with tarpaulins for the last

Correct and Incorrect Methods of Lacing Belts

will fail to give satisfactory service if not adapted for the use to which it is put.

In deciding upon the right belt for any particular service there are eight factors to be considered: (1) distance between pulley centres; (2) diameter of the pulleys; (3) width of the pulleys; (4) use of idlers, cone pulleys, quarter turn, half turn, etc.; (5) speed; (6) horse-power to be transmitted; (7) character of the load (jerky or constant); and (8) conditions such as contact with moisture, oil, or other deteriorating influences.

Over these factors the belt-man usually has little or no control. His problem is to take the conditions as he finds them, and apply a belt that will give the best service possible under the circumstances. Yet he may sometimes perform a real service by calling attention to a faulty arrangement, when the conditions are such that the fault may be corrected. Real economies may sometimes be effected by lengthening the distance between pulley centres, increasing

ten days, and two salamanders were kept burning under this cover. The laboratory and the underwriters' regulations for testing a 'fire-wall' provide that the sample shall be subjected for four hours to a heat ranging from 1000° within five minutes after the test is started to 1600° at one hour, and up to 2000° at four hours. The curve of the readings made in this test followed this theoretical curve closely. In addition it also provided that the face of the wall away from the flames shall not become hotter than 300°. When the first sample had been under heat for about 18 minutes a considerable spalling of the face occurred between one of the studs and the abutment about 18 in. away, but this had been expected as previous experiments had shown that gunite slabs demanded considerable opportunity for expansion between fixed points. In fact a hole about 15 in. diameter was opened up through the side toward the fire, but even with this handicap the sample was subjected for four hours and fifteen minutes to the heat above indicated without any sign of breaking. The heat was withdrawn at this period because of the fact that one of the outside thermometers showed a little more than 300°, although all the other four thermometers read considerably less. Strange to say the thermometer that showed the high reading was farthest away from the hole that had broken through the inner wall. The second test made on June 4 called for a similar sample to be subjected to heats up to 1600° for one hour, at which time the frame was removed from the furnace and the sample swung over so that it could be subjected to a stream of water through a 1½-in. nozzle at 50 lb. pressure for five minutes. This sample at about the same period as the first sample showed similar spalling and a hole at almost exactly the same spot. The general impression was that the greatest initial heats were at the end of the furnace, and that when the stress on the short span was once relieved no further trouble occurred. When the water was thrown against the wall considerable cracking occurred, and after cooling it was seen that the slab had split for some distance back from the slabbing-point due to a lamination along the plane of the wire mesh. None of the material fell, however, nor was there the slightest spalling of the gunite. This led to the recommendation that the mesh be placed as near the centre of the slab as practicable in a wall of this kind, in order to allow for a considerable thickness of undisturbed material behind the wire if such lamination should occur.

It is uncertain pending the issuance of the official report exactly what the ruling will be, but inasmuch as all of the gentlemen present seemed to be satisfied, and in view of the statement made by one of them that he considered this wall "better than a 12-in. wall", it seems certain that gunite walls will be accepted as self-supporting 'fire walls' under certain conditions in steel or reinforced-concrete structures. No tests have ever been made to show the value of concrete walls under similar conditions, but tests that have been made on concrete have indicated that gravel concrete will stand only a small amount of heat; that granite concrete breaks down under the water-test; that trap-rock and gravel concrete fuses and flows at 1800° to 2000°; but that a high-grade limestone concrete will withstand these heats. Offsetting this, however, is the fact that most of the limestones obtainable are not suitable. Also it is noted that, if limestone or slag screenings were used as the aggregate in gunite, even better results still would probably have been obtained, as the sand used in these tests was highly silicious. Gunite is much used for fire protection in the larger mines throughout the United States where timbers in shafts, stations, and other more or less permanent working passages are coated with a layer ¼ to ½ inches thick.

Bulletin L 531-B, issued by the Worthington Pump & Machinery Corporation, describes Laidlaw 'feather-valve' air-compressors.

COMMERCIAL PARAGRAPHS

The C. L. Best Gas Traction Co. announces the establishment of its sales and display room at 730 Van Ness Avenue, San Francisco. The product of the company will be on display and full information regarding Best 'tracklayer' tractors may be obtained.

B. V. E. Nordberg, son of the pioneer engine and hoist-builder, B. V. Nordberg, has been appointed sales manager for the Nordberg Manufacturing Co., Milwaukee. H. W. Dow, former sales manager, recently resigned to become vice-president and engineer for the Forest Products Chemical Co. at Memphis.

At the annual meeting of the stockholders of the Westinghouse Electric & Manufacturing Co. held at East Pittsburgh on June 9, the following directors were unanimously re-elected for three years: Guy E. Tripp, chairman, Joseph Marsh, president of the Standard Underground Cable Co., H. H. Westinghouse, chairman of the board, Westinghouse Air Brake Co., Albert H. Wiggin, chairman of the board of the Chase National Bank, and George W. Davison, president of the Central Union Trust Co., was selected to succeed James N. Wallace, deceased, for the term expiring in June 1921.

Recent advertisements of the Westinghouse Union Battery Co., Swissvale, Pennsylvania, have, unfortunately, led many to assume that the Westinghouse Electric & Manufacturing Co. was entering the storage-battery field. In order to clear away any misunderstanding, the Westinghouse Electric & Manufacturing Co. authorizes the statement that the Westinghouse Union Battery Co. is owned and controlled by the Westinghouse Air Brake Co., Wilmerding, Pennsylvania, and the Westinghouse Electric & Manufacturing Co. is not in any way connected with the manufacture, sale, distribution, or service of the product of the Westinghouse Union Battery Co.

The Chicago Pneumatic Tool Co., New York, announces the election of Allan E. Goodhue as vice-president in charge of sales. Mr. Goodhue since May 1, 1919, has been managing director of the company's English subsidiary, the Consolidated Pneumatic Tool Co., London; also director of European sales for the Chicago Pneumatic Tool Co. Mr. Goodhue was formerly for a number of years connected with the sales department of the Midvale Steel Co. and Midvale Steel & Ordnance Co. in Philadelphia, Chicago, and Boston, leaving that company in March 1918 to enter the service of the Government. From that time until January 1, 1919, when he became connected with the Chicago Pneumatic Tool Co., he was assistant manager of the steel and raw material section, production division, of the Emergency Fleet Corporation.

The General Fireproofing Co. in the May issue of its publication points out that the most important part of any industrial operation is the human part—the men who run it. Machines are important. Buildings are important. But they are useless without the men; whereas men could, in a pinch, make progress without either the machines or factories, as was the case before the invention of machinery. The house is one of the most important factors in shaping the true growth of the individual. Ramshackle dwellings cannot fail to impress their character upon their inmates, and ramshackle workers cannot fail to impress their character upon their work. The company believes that the question of proper 'industrial housing' is one of the most important considerations of the employer today and recommends permanent fire-resisting construction. Cement stucco on metal lath over reinforced concrete frame, produces a construction which is not only rigid and permanent, but possesses the insulating qualities so essential in exterior wall-work by having dead-air space, thereby keeping the building warm in winter and cool in summer.

Two-ton White operated by the Cananea Consolidated Copper Co., at Cananea, Sonora, Mexico. This owner says that White Trucks have given long, satisfactory service at a low cost of operation

WHITE *has the* OWNERS

THE real merit of a motor truck is strongly reflected in its owners. The Annual Roll Call of White Fleets in actual service is graphic proof of the most remarkable truck ownership in America, as remarkable for the quality of that ownership as for its extent and steady growth from year to year.

The Roll Call, including only owners of ten or more White Trucks, lists 350 concerns with a total of 12,674 Whites. All together there are 3,691 White Fleets comprising 40,919 trucks, exclusive of single-truck installations.

Behind it all there is one decisive reason: White Trucks do the most work for the least money.

Gas Combination Furnace Outfits

The firing in these furnaces is done on a tangent to the fire box, with the result that the flame does not impinge on the crucibles but surrounds and envelops them. This great advantage will be appreciated by experienced assayers and refiners who know how destructive it is to the crucibles to have the flame strike directly against them.

The crucible chamber is circular, which is the proper and natural form of a fire box, as such a form offers less corners and edges for the fire to act upon, as well as being the best form for proper combustion. Access to this chamber is to be had from either side of the furnace through covered apertures.

The cold furnace will be at a good working heat twenty min-

utes after starting the burner, and the muffle will be ready for use before the first melt is completed. The muffle capacity is equal to the melting capacity and will easily cupel all the melts possible to be made.

GAS BURNER

The gas burner used in this outfit is a simple, inexpensive, long lasting cast-iron burner; this operates equally well on either illuminating or fuel gas. Gas supply is controlled by valve in burner, while air supply is regulated by six-point regulator which is furnished with motor, this way of regulating air is much better than the usual way employed in the majority of outfits of this kind where they use a damper in the air pipe.

GARRATT JACK HEAD PLUNGER PUMPS

Are Not Affected by
Muddy, Gritty Water

The cylinder has large clearance and the plunger is outside packed at the top. The suction and discharge valves are fitted with bronze taper seats and are easily exchanged by removing bonnets. The Jack Head works altogether on the down stroke; the pump rod is made to weigh just half the amount of pressure exerted on the plunger so that the load is equal and uniform at all times whether on down or up stroke. In this way

Balance Bob is Eliminated

thereby increasing the efficiency and materially reducing cost of installation. These pumps are made with capacities of from 30 to 500 gallons per minute and for elevations up to 600 feet.

**FLEXCO-
LOK**
Lamp Guards

Mechanically Perfect
Easiest to Put On—Best in Service

Flexco-Lok Steel Lamp Guards are of expanded sheet steel heavily plated with non-corroding tin. Very simple in adjustment. Halves open on riveted hinges in base; close over lamp locking screws in collar. Strongly reinforced.

All Sizes—Locking or Plain

Flexco-Lok Steel Lamp Guards are made for all sizes of lamps for either standard brass or weatherproof sockets. Self-retaining lock screws in Flexco-Lok Guards lock with a key preventing unauthorized removal. We make also Flexco Steel Lamp Guards exactly the same construction, types and sizes but with plain round head screws.

OPPORTUNITIES

Under this heading announcements may be made of new and second-hand machinery or supplies, for sale or wanted. The cost is five cents per word, including address. Minimum charge one dollar per insertion. Remittances MUST accompany order. Copy must be received by Saturday for the following week's issue.

FOR SALE—One gold dredge, flume type $3\frac{1}{4}$ cubic feet buckets of nickel chrome steel with manganese lips; completely equipped with 90 H.P. Western Gas Engine, separate engine and dynamo for lighting plant, 60-foot flume with riffles, 14-inch Byron Jackson pump, blacksmith's outfit, etc. All new, never used; can be purchased for much less than present cost of manufacture. Address Straub Mfg. Co., 5th and Chestnut Sts., Oakland, Cal. tf

OPPORTUNITY—Diamond drilling on a new basis of cost, saving you one-half to one-quarter over present methods. Guaranteed work with best up to the minute equipment, efficient and experienced help. Long experienced and enthusiastic customers. Write for information. H. D. Staley, 229 Lick Bldg., San Francisco. tf

WANTED—Wood pipe, second hand, four to ten inch; telegraph quantity, location and price to O. H. Fairchild, Richfield, Utah. 7-17

HYDRAULIC EQUIPMENT FOR SALE—23,000 feet double riveted drive pipe, 11 in. to 30 in., with elbows, tapers, tees and gates; 3 Campbell elevators; complete inventory upon request. Address Opp. 392, Mining and Scientific Press. 7-24

FOR SALE—One 4-in. Empire prospecting drill, regular equipment, complete with horse-power sweep, spring attachment, 60 feet of rods, 90 feet of casing and many extras; in use only four months; original cost \$1400; bargain. Address Star Machinery Company, 1731 1st Ave. South, Seattle, Wash. 7-17

WANTED—Right parties to develop best copper prospect in Arizona; will consider lease or sale. Address Box 134, Jerome, Arizona. 7-10

WILL give controlling interest in group of claims at Ray, Arizona, for a certain amount of development work. Copper-silver, prospect stage only, but fine ground in proven district; close to railway; plenty of water. Address McKee Investment Co., Ray, Arizona. 7-3

FOR SALE—An electric traction shovel, Vulcan type, one and one-quarter yard dipper. For particulars address S. P. Colt, Hereford, Oregon. 7-24

WANTED—Compressor, two to four-drill capacity, together with suitable oil or gas engine; also drills and equipment; price must be right for cash. Address P. O. Box 772, San Jose, California. tf

The cost of advertising for positions wanted is 2 cents per word, including address. Minimum charge 50 cents per insertion. Replies forwarded without extra charge. Remittances must accompany order. Copy must be received Saturday morning for the following week's issue.

CHEMIST AND MILL SUPERINTENDENT, at present employed by large corporation, wants change; technical graduate; expert in flotation and leaching. Address Box 1067, Phoenix, Arizona. 7-24

SAFETY ENGINEER—Graduate engineer with eleven years general mining experience, at present engaged in safety and welfare work, wishes larger opportunity with corporation definitely pledged to this line and endeavor; organizer, capable and tactful; married; age 36. Address PW 391, Mining and Scientific Press. 7-3

DRAFTSMAN open for engagement; three years with mining, milling and smelting machinery companies. Twelve years with mining, milling and smelting companies. Address PW 375, Mining and Scientific Press. 7-3

MINE CHIEF CLERK wants position; available after July 1; age 45; single; five years of experience; able to handle all office work, including monthly cost sheets, all by himself, for mine employing 50 to 100 men; speaks Spanish; good references; minimum salary to start, \$225. Address PW 388, Mining and Scientific Press. 7-3

POSITION WANTED—Master mechanic, mine, mill, power house construction; 20 years experience; references from past employers. Address PW 390, Mining and Scientific Press. 7-3

MINING ENGINEER, experienced and efficient superintendent and manager, open for engagement; age 43; references A-1. Address PW 384, Mining and Scientific Press. 7-17

MINING ENGINEER open for engagement; 20 years executive experience in the Southwest and Mexico; thoroughly conversant with both technical and business end of mine and mill operation; fluent Spanish; highest references. Address PW 383, Mining and Scientific Press. 7-17

MINING ENGINEER available for exploration work or mine and mill management anywhere except Mexico. Salary \$300; single; speak Spanish. Address PW 382, Mining and Scientific Press. 7-10

MILL FOREMAN OR SHIFTBOS; first class all around millman; extensive experience both flotation and cyanide; can do assaying; good mechanic; speak Spanish; go anywhere. Address PW 381, Mining and Scientific Press. 7-3

MINE FOREMAN OR SHIFTBOS at present employed desires position with a responsible mining company in the western United States; have had 15 years good practical experience as miner, timberman, etc.; four years as shift boss and foreman; thoroughly understand the care and operation of pumps, compressors, etc.; 45 years of age; married; will be available on the first of July. Address PW 377, Mining and Scientific Press. 7-3

COLUMBIA E. M., ten years experience in both operation and engineering as mine foreman and chief engineer respectively; speak Spanish. Address PW 371, Mining and Scientific Press. 7-3

SUPERINTENDENT gold mine and mill; 25 years experience; thorough assayer, machinist and millwright; mill planning and construction; have well-equipped assay outfit. Address PW 336, Mining and Scientific Press. 7-3

MILL SUPERINTENDENT of wide experience desires employment; just completed five-year job; go anywhere; know how to handle men and machinery. Address PW 367, Mining and Scientific Press. 8-7

MINING AND SCIENTIFIC PRESS wants a permanent circulation representative in every mining community in the world. Replies will be held confidential if desired. Address The Manager, Mining and Scientific Press.

PRACTICAL MATHEMATICS FOR HOME STUDY

By CLAUDE IRWIN PALMER

493 pp.

\$3.00

Fabrikoid

Arranged in four parts:

Arithmetic with Applications

A concise treatment of the subject with checks of progress, degree of accuracy possible in solutions, and contracted processes.

Geometry with Applications

Facts and principles involved in the solution of geometrical problems are thoroughly discussed, bringing into play the devices and methods used by practical men.

Algebra with Applications

Considers graphical methods and the application of equations to practical problems.

Trigonometry and Logarithms

Giving many applications and emphasizing those parts that may be applied directly to practical problems.

POSITIONS AVAILABLE

Announcements in this column are secured through the co-operation of many of the largest mining companies in the United States. Advertisements under this heading will be inserted two times without charge. Additional insertions charged at the rate of 2c. per word, including address.

WANTED—Young man who has taken partial or full university mining or mechanical course; preferably one who has spent his vacation period in employment in metal or coal mine. Desirable permanent position with advancement opportunities is offered to one who is a business student and with live commercial spirit. Applications are invited from young men graduating this year or those who have been out one or two years. Please give personal description, educational details, and three references. Answers will be held strictly confidential and full information concerning position open will be given to those whose application letters warrant it. References are asked to establish applicant's standing, and will not be communicated with until negotiations have been opened with applicant. Address PA 374, Mining and Scientific Press. 7-3

CHEMIST wanted for Western smelter; thoroughly familiar with inorganic determinations. Give experience, references and salary expected. Address PA 385, Mining and Scientific Press. 6-26

WANTED MINERS—Two first-class practical miners with modern experience in drilling, timbering and pumping, for gold company in Ecuador, South America, forty-five miles from coast, altitude 2500 ft.; climate good; salary \$150 per month, commencing from date of arrival at mine to return in New York, together with traveling expenses from port of sailing both ways, provided two years contract is completed; also board and quarters furnished; knowledge of Spanish desirable; only those with best references as to ability and character need apply. Address J. W. Mercer, 922 Equitable Bldg., Denver, Colo. 7-3

POSITIONS SECURED PROMPTLY for well qualified men in all branches of mining and metallurgical work; 17 years established clientele with the largest companies in the industry. Wanted immediately: zinc smelter superintendent, Arkanass, \$225; junior chemists, Utah, Tennessee, Illinois, \$140; flotation operator, northwest, \$175; 2 cyanide shift bosses, Nevada, \$165; coal mine surveyor, Colorado, \$175; mill draftsmen, Arizona, Minnesota, \$225-\$275. Apply Business Men's Clearing House, Denver, Colo. 7-3

OPENING for experienced mine foreman and shift-boss with large mining company in Mexico. A knowledge of Spanish essential. Address J. I. Kane, 1112 Mills Bldg., El Paso, Texas. 7-3

The JACKSON ROTARY COMPRESSOR

Is "Every Mines' Compressor" from prospect to the largest developed property.

You can't carry a Jackson Rotary Compressor around in your pocket, but you can do the next thing to it.

It is so compact, that it can be lowered down the smallest shaft.

It is light enough to be readily portable; it is self-contained, of course.

Whether underground or on the surface, the Jackson Rotary is one of the most effective, useful appliances made for mining operations.

Nordstrom Lubricated Plug Cocks.

IN REPLY PLEASE REFER TO

A. C. White

The Merrill Co.
121 Second Street,
San Francisco, Cal.

Gentlemen:

In conformity with my letter of Nov 19th 1919 and your reply of Nov 24th 1919 beg to submit the following report on one of your 2" plug cocks installed on one of our strong Sulphuric Acid lines.

Installed	11-21-19	open
Closed	11-21-19	8" wrench
Opened	12-3--19	8" " "
(Closed)		
(Opened)	12-17-19	using lotick of lubricant & 10" wrench.
Closed	1-1-20	10" wrench
Opened	1-16-20	10" " "
Closed	1-17-20	10" " "

You will note that only once since the installation of this cock have we needed to put lubricant into it to make work. We are very much pleased with the results we have had so far with this cock as any other kind of valve we have used had to be moved at least once in 24 hours to keep it free, or at least to be positively sure it would work when wanted.

Would it be possible for you to furnish us with a lubricant that will stand 180 degrees Cent.? We have one other place where we would like to try one of these cocks but the material passing thru the line frequently rises to the above mentioned temperature.

Kindly let the writer hear from you at your early convenience.

Very truly yours

Arthur C. White
Calcium-Magnesium Products Div.

PELTON

20 foot head PELTON Turbine connected through speed increasing gears to
115 ft. head PELTON Pump.

WATER POWER FOR PUMPING

Very satisfactory savings
can be made in pumping
costs by the installation of
all-hydraulic pumping equip-
ment.

First costs are kept at the
lowest point as only one
power unit is necessary. The
water wheel or turbine de-
velops the power and trans-
mits it direct to the pump
shaft. Operating costs are
practically zero as there are
no power nor fuel bills to
pay.

The maximum amount of
water can be pumped. No
loss occurs between the
power unit and the pump.
Both are designed to oper-
ate with high individual effi-
ciency. When speed changes
are necessary, high efficiency
gears are installed to pro-
vide proper ratios with very
small losses of power.

Let us give you details.

THE THOMPSON BALANCE CO.
Denver, Colo.

GANDY,

the original stitched COTTON DUCK BELT, has all the strength of a steel cable with the tenacity, flexibility and longevity of specially processed cotton duck.

GANDY is the standard belt of industry.

Its enviable reputation is based on the performance of nearly 40 years in the transmission and conveyor field.

GANDY engineering service goes with every belt—power or conveyor—to insure the right belt—in ply and size—for each particular job.

Orders filled promptly from mill supply house or direct.

Salt Lake City, Utah

Old Drifts and Cross-Cuts Sealed up with GUNITE

Are *EASILY* done and are out of the way permanently.

The constant menace of abandoned workings can be easily removed. Fire risk can be thus reduced and your men protected from sagging roof or rotting timber.

With the "CEMENT-GUN" it's simple

All you have to do is to lay up a dry stone stopping and shoot on the Gunitite to whatever thickness you desire. Then any floods, breaks, gas or fire that break out in the drift will be blocked and your men protected.

LET US SHOW YOU HOW IT CAN BE DONE

MANUAL OF CYANIDATION

By E. M. HAMILTON

277 PAGES

PRICE \$3.00

7 1/2" x 5 1/4"

Pocket Size

Flexible Fabrikoid Binding

A practical handbook on the cyanide process, including the latest information and inventions. It presents in convenient form the essential data having a practical bearing on testing an ore, planning the flow sheet and operating the plant when erected.

All tables pertaining to the cyanide process as well as formulas and standardized tests, are given.

ATTENTION ENGINEERING PROFESSION

REPAIRING OF SCIENTIFIC INSTRUMENTS

When your surveying instrument meets with an accident it warrants placing in reliable hands. Mechanics cannot be expected to intelligently put a scientific instrument in order, despite a conscientious effort on their part. A mechanician trained for years in this particular work can make the necessary repairs in shorter time and with the interest of the profession constantly in mind.

We, with our factory facilities and trained workmen, can assure the profession of the utmost satisfaction in the repairing of all makes of surveying instruments, and we assume all responsibilities when this work is entrusted to us, for the work of our help is fully guaranteed.

The necessary charges for such work represent nothing more than the time, carefully tabulated, and actually required by only skilled mechanics to put the instrument in first class condition; this being supported by the integrity of a firm established in San Francisco since 1882.

Delays may ensue, for we are at present entrusted with the repair of many instruments, but we solicit your work, assuring you that it will be handled as quickly as possible.

Estimates are cheerfully made.

REPAIRS ALSO MADE TO ANEROID BAROMETERS, HAND LEVELS, STEEL TAPES, DRAWING INSTRUMENTS AND OTHER SCIENTIFIC INSTRUMENTS.

THE A. LIETZ COMPANY

Established 1882

Main Office and Salesroom: 61 Post St., San Francisco, U. S. A.

Prospector's Field Book and Guide

In the Search for and the Easy Determination of Ores and Other Useful Minerals
By H. S. Osborn
NINTH EDITION, THOROUGHLY REVISED AND ENLARGED
By M. W. von Bernewitz

4 5/8 x 7 1/8 400 Pages 57 Illustrations Flexible Binding Pocket-Book Style

Price . \$3.00

A new addition to this splendid book is a spirited introduction emphasizing the necessity of prospectors receiving some technical training. Discusses practical mineralogy, crystallography, the value of the blowpipe in prospecting, surveying, and chemical tests in the field. Separate chapters are given to the precious and base metals, also to the non-metallic metals.

An important guide and a suggestive aid throughout the new book are the many brief descriptions of ore deposits of all minerals occurring in scattered parts of the world. These have been abstracted carefully, and tell how certain minerals may be expected to be found. Another special feature is the lists of outfits, prices and the manipulation of the apparatus. In the appendix will be found numbers of useful tables, an explanation of the unit system of buying and selling ores, and a complete glossary of mining and mineralogical terms.

USE THE COUPON

You will be interested in our latest catalogue which contains a description of the best and latest books on industries allied to the mining field

MINING AND SCIENTIFIC PRESS

420 Market Street, San Francisco

Gentlemen: Enclosed find \$3.00 for which send me one copy of Osborn—Prospector's Field Book and Guide.

Name

Address

It is understood, if the above book proves unsatisfactory I am at liberty to return it within ten days and refund will be made of the purchase price.

HCB 7-3-'20

Aldrich Pumps

FOR GENERAL SERVICE

Quintuplex Motor Driven Pot Chamber Pump, for general pumping requirements such as water works, steel mills, factories, etc., but is especially suited for mine service. Can be run with one or two motors, mounted on top. Their range of operation is from 300 to 4000 G. P. M. against lifts of from 500 to 1000 feet.

GARFORD

The Garford Definite System
of Service to individual truck
owners has been fundamental
in the accomplishment of
Garford Low Cost Ton-Mile.

Garford

Lima, Ohio

Periodically during each year Garford expert service men go from our factory to every Garford owner. They thoroughly inspect each truck, ride with the driver on the job, and make minor adjustments. Written reports of these inspections are sent to factory for analysis, and recommendations are made direct to owners by our Maintenance Department.

Taylor Spiral Riveted Pipe

346 Pounds Pressure

Incaoro Mines, near LaPaz, Bolivia, S. A.

"The handling of all this material was particularly severe, as it had to be transferred twice at New York, several times at the Isthmus of Panama, again at Mollendo, and many times more during the inland journey, ending with a haul of 120 miles on the backs of mules. In all, there were more than twenty transfers of each shipment, yet the material was so well packed, and was itself so substantial (particularly the Forged Steel Flanges), that there was no loss by breakage.

"Your pipe and your promptness in shipping, I can only say affords a great favor to anyone in a distant country, and I cannot recommend it too highly.

"Very truly yours,

"(Signed) D. C. BRICKER, Gen. Mgr.,

Catalogue and Special prices on request.

"Incaoro Mines."

AMERICAN SPIRAL PIPE WORKS
Chicago, Ill.

The Foremost Dewatering Device

The Highest Development of the Modern Filter

The Portland Continuous Filter

Filters heavy tonnages of flotation concentrates rapidly and inexpensively.

Delivers concentrates direct to cars or bins with a moisture content frequently as low as 8 or 10%. It pays for itself by reducing shipping costs and eliminating waste in handling.

Every Portland is a complete machine. Patented features give unequaled precision and ease of adjustment, even delivery of evenly dewatered cake, low upkeep and steady service.

Used by the foremost mining companies, Smuggler-Union, Portland Gold Mining, Utah Copper, Timber Butte, American Zinc, Chino Copper, U. S. Smelting, Ref. & Mining, Butte & Superior, Nevada Cons., etc.

There is a very strong probability that the Portland Continuous Filter can make your mill earn additional profits. Send for a copy of new Bulletin 28-C and see.

No anxiety about patent litigation, no royalty to pay. We guarantee that the Portland Continuous Filter does not infringe any legal rights of other patent owners.

Cleveland Products Are Built for Hard Work

Cleveland "Pocket-In-Head" Rotators are quality products. Every detail in construction has been so perfected as to deliver the greatest service. Drop forgings have been used throughout. The steel is carefully selected, the machinists who make Cleveland drills are all experts in this line and the majority of them have been in the company's employ for years and take real pride in maintaining our high standard.

The result is a product that will not fall down on the job but which will deliver a greater footage at a lower cost.

Marcy Mills Are Made For Any Capacity Plant

It is worth your while to investigate the Marcy "One Easy Step" method of ore reduction, even though your plant be small.

The same savings in crushing costs being made in large operations as at Inspiration, Braden and Kennecott, are possible in your own smaller mill.

The Marcy patented discharge is only one of many features which distinguish the "One Easy Step" method.

Literature describing the Marcy Mill best suited to your requirements will be sent if you will write an outline of conditions.

T. A. RICKARD, . . . Editor

WE take pleasure in publishing a description of the structural geology of the Las Chispas mine, in Sonora; by Mr. Fernando Montijo Jr., the Mexican engineer in charge of the property. It is gratifying to see the native-born taking a proper part in the development of the mineral resources of the country; it is also pleasant to find a Mexican technician so well able to express himself in our language.

AT a time when the high cost of everything, including government, is impressed upon all of us, it is regrettable that fifty Congressmen, with their wives and families, should start on a junket to the islands of the Pacific at the expense of the taxpayers. The transport 'Great Northern' sailed on July 5 with this party aboard. It is to be "a long cruise" among the islands, including the Philippines. We would like to know who authorized this public extravagance and what excuse there is offered for it. One of our local Congressmen is in the party; he should be asked to make an explanation.

ON another page we publish an article on the electrolytic separation of copper from copper-cobalt-nickel matte as performed at Fredericktown, Missouri. The article is by Mr. R. G. Knickerbocker, who described the incidence of bolshevism on mining in Siberia in our issue of May 8. Mr. Knickerbocker is now smelter superintendent of the Messina Transvaal Development Company, for which Mr. A. B. Emery is resident manager, in the Transvaal. The results of experiments and investigations into the production of a suitable solution of nickel and cobalt are given frankly, and they should prove helpful to others in like difficulties. It is rarely that the record of such work is given for publication, yet it is exactly the kind of information that is most useful.

IT is about time that San Francisco had a real morning newspaper. The Democratic convention adjourned on Saturday night at 11:40, after the 22nd ballot, yet the 'Examiner' of Sunday morning had no news later than the 20th ballot, whereas the 'Chronicle' did tell its readers that the Convention had adjourned, but failed to give the figures of the last ballot. On the following Tuesday morning the 'Chronicle' on its front page announced a deadlock at the 41st ballot, although shortly after midnight Governor Cox had been nominated. Of course, the people of this community know that both our morning

papers go to press in the evening and are on sale soon after nine o'clock; both are belated evening papers; but the delegates from other cities must have remarked the pitiful lack of enterprise exhibited by both of them in failing to make an effort to record the doings of the Convention with some degree of promptitude. Owing to its geographical position, San Francisco offers extraordinary opportunities to a wide-awake publisher, but unfortunately our miserable morning newspapers are as noteworthy for the lack of worthy enterprise as they are notorious for their meanness and untrustworthiness.

STATISTICIANS of the Department of Agriculture declare that the country-wide shortage of farm labor has been constantly increasing until now it is 28%. There is no reason to doubt that this figure is approximately correct and it is entirely logical to conclude that unless there come a change the farmers will not be able to produce sufficient foodstuffs to supply the hundred million people in our own country. Even if the farmers could by extraordinary effort supply the deficiency, they would not do it; nor should it be expected of them. With an under-supplied market the same amount of profit can be obtained from 75 bushels of potatoes or 75 hogs as can be realized from 100, and like the rest of us the farmer sees no reason why he should not take advantage of his position. That is one reason the prices of foods are not coming down with those of some other commodities. The only solution is a return of workers to the farms. This may be brought about by a further increase in the prices of farm products to a point that will influence more people to engage in farming for themselves, and attract laborers to seek work on the farms at higher wages than they are getting in the so-called industrial occupations, which now offer a number of agreeable advantages in addition to better pay. An alternative is a sudden depression in industrial activity that would force the workers to seek employment in agricultural occupations rather than be idle. Whether we are engineers or laborers, merchants or clerks, we are interested in the farmer and the farm as being the source of that first essential commodity, food. Food we must have; but we will have to pay for it at a rate such that after sundry retailers, wholesalers, brokers, and packers have taken a toll there is enough left to make it worth while for someone to produce it. There are many angles to the problem, but it is safe to say that hope for material gain, rather than

an altruistic sense of responsibility to a hundred million stomachs, will re-fill the places of the missing 28%.

ACCORDING to the report of the third annual meeting of the Anglo-American Corporation of South Africa, that enterprise is making satisfactory progress. We note that Mr. Walter McDermott has joined the directorate, largely in consequence of the absorption of the Rand Selection Corporation, a subsidiary of the Consolidated Mines Selection Company, a successful enterprise with which Mr. McDermott has been identified from the start, in 1897. The Anglo-American has acquired the controlling interest in the Consolidated Diamond Mines of South-West Africa, which owns the diamantiferous area in the former German territory. A report was presented to the meeting by our friend Mr. W. L. Honnold, an American mining engineer well known in our West, and, as we recall, a graduate of the Michigan College of Mines. Mr. Honnold used to be manager of the Brakpan mine on the Rand. He gave an interesting description of the gravel from which the diamonds are washed, and quoted an estimate indicating that the diamond-field should yield 15 million carats. We note that the four principal diamond-producing companies in South Africa have agreed to restrict the production, each company being allowed a prescribed quota. The amount of annual sales is fixed at £12,000,000, of which De Beers is to contribute 51%, South-West Africa 21%, the Premier 18%, and Jagersfontein 10%. The minor producers are left to their own devices, which must be a comfort to them. The Anglo-American Corporation also holds blocks of shares in mining companies on the Rand. Mr. E. Oppenheimer, the chairman of the meeting, and of the corporation, stated that the premium on gold has been entirely absorbed by the increased expense, due to higher wages, the advance in the cost of supplies, the rise in banking exchange on London from Johannesburg, and the lessened efficiency of labor. The corporation is capitalized for £4,000,000 and has paid a dividend of 5% on account of the first half of the current year.

PERHAPS the most ludicrous thing at the Democratic powwow was the speech of Mr. Charles F. X. O'Brien, who placed before the convention the name of Governor Edwards, banker, vestryman, teetotaler, but avowed champion of the 'wet' cause. The speech was all the funnier because Mr. O'Brien had an impressively pompous demeanor; he took himself with exceeding seriousness—possibly to make up for the lack of it in the attitude of the delegates toward himself and his candidate. If, 40 years ago, before even Kansas had given prohibition a serious thought, some foe of booze had hired a yeggman to break into the vault wherein the Constitution reposes, and had in the middle of the night inscribed the 18th amendment on that revered document; and if the Supreme Court, upon discovering next morning the presence of this revolutionary addendum, had decreed, sapiently, that what has been writ could not be unwrit, but must become the law of the land; if these remarkable events had transpired, the speech of Mr. O'Brien might

then have been comprehensible. His contention was that the people should have had a voice in a question of such serious moment; but that since by some mystic chicanery this amendment had been foisted on us, a candidate should be named for President who would make it his purpose to enable "the citizenry of the great and glorious, etc.", to raise its voice in protest. We can appreciate the argument of those who believe that the amendment infringes upon their personal liberty; we can sympathize with those who were wont to worship at the shrine of John Barleycorn; but we have no patience with the man who is so stupid as to insist that prohibition was put over on the people by some exterior force without their knowing it. What about the 45 States that have collectively and individually ratified the amendment? If the liquor people or anyone else want to continue the argument why not advance this line of reasoning: "By an overwhelming majority we let ourselves in for something. Having found out how it works some of us are sorry. Perhaps there are enough sorry ones to carry a vote for reconsideration."

COMPLYING with the order of Federal Judge Bourquin in the suit of Minerals Separation against the Butte & Superior company for alleged infringement of froth-flotation patents, the defendant has filed a complete record of operations since 1911 when its ore was shipped to the old mill at Basin, Montana, for the purpose of developing a satisfactory scheme of treatment. A complete record of ore mined and milled, concentrates produced and marketed, costs, and earnings is included in these data and the terms of the contracts under which the product was sold to sundry smelting companies are given. Some months ago the Butte & Superior filed an accounting in which it calculated that approximately \$400,000 represented the difference between the actual proceeds from the company's operations and what could have been obtained if the patents of Minerals Separation as defined by the decision of the Supreme Court had not been infringed. This was not satisfactory to the owners of the patents. They obtained the order for the additional data, which have now been furnished, and from them the experts doubtless will proceed to calculate supposed damages running into millions of dollars. Last week Mr. Huston Thompson, of the Federal Trade Commission, opened hearings in San Francisco against Minerals Separation, on the charge of using unfair and coercive methods in attempting to prevent legitimate use of the flotation process.

THE prospect in Mexico is less gloomy than for many months; in fact at the moment the outlook may conservatively be described as cheerful. It is true that Pancho Villa has been entertaining himself at the expense of Generals Jesus Guajardo, Ignacio Enriquez, and Joaquin Amaro, but General Eugenio Martinez and Col. Sandoval are about to take command and these sterling soldiers are expected to comb the mountains of Chihuahua until Pancho is apprehended. We wish them well. General Jacinto Trevino, Secretary of Commerce and

Industry in the cabinet of Provisional President Adolfo De la Huerta, has not as yet agreed to nullify the objectionable restrictions regulating drilling for oil that were instituted by the Carranza regime, but he has shown a willingness to consider the contentions of the oil companies. This attitude has increased confidence among the American and other interests, and record production is being made. More than 11 million barrels was shipped during May and the Standard of New Jersey recently brought in a new well with a daily capacity of 100,000 barrels. It is reported that trains are running without military escort, an unusual thing in the country south of the Rio Grande; the Government has ordered the return of property confiscated years ago; and General Elias P. Calles, Secretary for War, has diverted the energy of many of the soldiers from plundering to road-building and other profitable work. Other indications of a return to normal are labor strikes at Puerto, in the State of Vera Cruz, and at Leguna, in Coahuila. General Calles, upon being appealed to, ordered the release of union leaders, who had been arrested, declaring as he did so that "the right to strike is sacred". Reports from Sonora are to the effect that the outlook has stimulated mining activity. A number of mills have resumed operation lately and several old mines are again producing, while at others unwatering has been started. At Nacozari the Phelps Dodge Corporation is planning to double the capacity of the Moctezuma concentrator, the project including the installation of seven new Diesel oil-engines. According to 'El Democrata', all of the political factions have agreed to support the candidacy of General Alvaro Obregon and he will presumably be chosen President at the general election, which has been set for September 5. Whether or not these favorable reports reflect the true state of affairs, and if so, whether this is simply a lull before another storm, is hard to say. It is difficult to believe that any radical change has taken place, and that the fundamental causes for turmoil have been removed, but if there is ever to be lawful order and peaceful industry a start must be made some time. Let us hope that the time has come.

Bad Language

A few days ago we picked up a paper on the mining industry of Joplin presented before the recent meeting of the Zinc Institute at Chicago. We were impelled to read it because it bore the name of a man whom we knew to be a competent mining engineer. After reading a couple of paragraphs we laid it down in despair, because we found ourselves unable to follow the author in his statements concerning the condition of mining in that Missourian district. The reason for our bewilderment was the use of terms to which a local meaning was attached. It is more than probable that other readers, even those familiar with the literature of mining in places in which the language of America and of several other countries is spoken, would have been non-plussed as we were. The author of the paper in question, in accord with local usage, wrote of "ores" when he meant 'con-

centrates', namely, lead concentrate and zinc concentrate. When he spoke of "blende ore" and "calamine ore", he meant the mill-products containing a high proportion of the sulphide and the silicate of zinc, respectively. It is not his fault, nor ours, that in Europe the name 'calamine' stands for the carbonate of zinc, and that there the silicate is called 'smithsonite'. This is mentioned by the way, just to suggest the need for the adoption of a uniform nomenclature. Moreover, in Missouri, it appears, they talk of a "lead ore" and a "galena ore" interchangeably, although they differentiate between a "zinc ore" and a "calamine ore". Again, the "ore" may be the crude, but selected, product from the mine or it may be the concentrated product from the mill. To tell the truth, we had intended to publish the Joplin article in this paper, because it was a good review of the progress of the industry in that district, but we were not sufficiently confident of the meaning of the terms used to be able to translate them into correct technical English, although we have been to Joplin and know something of the local lingo. Therefore we did not feel warranted in editing the paper for the benefit of our readers, who otherwise would have been unable to understand it. We ask, what chance had an intelligent reader at London, Melbourne, Shanghai, Vancouver, or Lima of understanding this paper as read before the Zinc Institute at Chicago? A plague on these localisms! They are not even discriminating in their own way, largely because they reproduce the usage of the stope and mill. As we have said often, it is well for us to go to the miner and the mill-man for knowledge concerning the mining and milling of ore, because that is *their* special business, but why in the names of Roget and March should technical writers, who are supposed to be specialists in *their* business, which, among other things, is to write intelligibly, go to the artisan and the mechanic for the terms they use in their writing or speaking? Joplin is not peculiar in its adoption of a half-baked terminology. At Central City, Colorado, it is the established custom to speak of the pyritic concentrate, containing gold and silver, and sometimes copper, as "tailings". There used to be a regular trade in "tailings", this mill-product being bought in small lots by brokers for the purpose of preparing a mixture upon which advantageous terms could be obtained from the smelters at Denver. Everybody spoke of "tailings", when they meant not the discard or refuse from the stamp-milling and bumping-table operations, but the valuable sulphidic concentrate. Such usage beggars language. To say it is unscientific is not enough; it is puerile. In Boulder county, Colorado, the miners speak of "hornblende", when they mean the dark agatized quartz, 'hornstone'. Shall we copy that blunder and introduce it into the literature of mining, just because some excellent single-hand miners happen not to know what they are talking about? In the Michigan copper country they call their ore "rock" and their crushing-plant at the shaft a "rock-house". They do not use the term 'ore'. Only last week a distinguished engineer, formerly connected with the Calumet & Hecla, told us that it was his understanding that the word 'ore'

could not be applied properly to an economic mine-product containing metal in the native state, and that "copper rock" was as correct, for example, as "gold quartz". The answer is that both are technically incorrect, the verbal coinage of unscientific people unable to speak or write with discrimination. The "gold quartz" of California is a misfit, because the ore of the Mother Lode, for example, contains only a minor proportion of quartz, the preponderant constituent being slate. Gold is associated with quartz in most veins, all over the world, but not in all; the product of the mine usually contains some quartz and a minute proportion of gold, so that "gold quartz" is not accurately descriptive; moreover it ignores the economic factor, that is, whether the proportion of gold is sufficient to make the rock an 'ore'. This last is a term with which we cannot afford to play fast and loose; it is defined as rock containing a valuable mineral in such proportion as to constitute an economic product, that is, one that can be exploited, at a given time and place, profitably. The idea of profit is implicit, for mining is performed for the purpose of making money. 'Mineral', of course, includes native metal; native copper is as much a mineral as chalcocite, native silver as argentite, native gold as calaverite. "Copper rock", on the face of it, means a rock containing copper or made up largely of copper; but the idea of profitable exploitation is not there. "Copper ore" carries the essential significance of economic value. The test is to take such local vulgarisms as those we have quoted from Joplin, Central City, Houghton, and Sutter Creek, and ask persons well informed in mining affairs in other districts what they mean. The misleading character of these spurious terms will then become manifest, for their descriptive value will be found to be far below par; they pass current locally, like the token coinage of a depreciated currency.

To some people exactitude in these matters is meticulous. They do not realize how spurious words get into use in consequence of a careless attitude on the part of those who ought to know better. It is common to speak of "slack lime" or "slacked lime", when, of course, the right word is 'slake' or 'slaked'. "Slack" means nothing in regard to lime; 'slake' is beautifully descriptive of the manner in which lime absorbs water with a sizzle, like a thirsty man on a hot day. The same people talk of a "larry", which is not a word in our language; they mean 'lorry'. They use such abstract terms as "capping" and "filling" in lieu of the concrete and precise 'cap' and 'fill'. They use "muck" and "dirt", which signify nothing. "Feldspar" came into use simply because Kirwan in his book on mineralogy failed to detect a typographical error, whereby a 'd' was inserted in 'felspar'. A majority, it is sad to say, of technical men use 'data' as if it were a singular and as if it were a synonym for 'information'. Many miners speak of "stratas". Are we to be the unprotesting victims of such illiteracies? Is it not worth while to preserve our language from such corruptions for the sake not only of our literary inheritance from the great ones of the past, from Chaucer and Shakespeare, from Addison and

Ruskin, but also for the sake of that precision of expression upon which all scientific writing depends if it is to serve as a means of exact statement?

The Work of Congress

Tradition was perpetuated by Congress in the session that began on December 1 and ended just in time for the Republican senators to participate in the 'deliberations' at Chicago last month. Much was said and little was accomplished in the way of passing bills. The Railroad Transportation Act, establishing the Railroad Labor Board, before which hearings are now being held in Chicago on the proposed increase in wages, and the Water Power Act, which should stimulate the development of hydro-electric projects for industrial power, were among the few important pieces of legislation actually accomplished. A number of bills of particular interest to the mining fraternity were introduced. The War Minerals Relief Bill, designed to permit appeal from the decision of the Interior Department to the Court of Claims or the Supreme Court, was passed by the Senate and reported by the Mines committee of the House, at which point progress was arrested. Representative McFadden's bill providing a premium on newly mined gold and at the same time placing an excise tax on gold used in the arts and industries, was the subject of a series of hearings before the House Committee on Ways and Means. It will repose there until next December. The Senate Committee on Finance reported bills previously passed by the House that provide a tariff of magnesite, tungsten, and zinc. Efforts to reach a vote on these measures were unavailing because of the pressure of multitudinous other affairs. Bills providing for duties on antimony, baryte, chromium, graphite, manganese, mercury, molybdenum, pyrite, and potash are pending before the Ways and Means committee of the House, and similar bills are in preparation dealing with mica, tin, and lead. A bill recently introduced provides for the creation of a division of mines and geology in the Department of the Interior with an Assistant Secretary of the Interior as the executive head. He shall be technically qualified by experience and education to direct the affairs of the division, which shall undertake the present activities of the Bureau of Mines and the Geological Survey, together with such other work related to mining, metallurgy, and geology as shall be designated by the President. The purpose is to do away with the duplication of effort, and to co-ordinate activities of the several offices. The creation of the proposed Department of Public Works, which would result in the partial reorganization of the various major departments of the executive branch of the Government to consolidate in a systematic way all engineering work, except the purely military, appears to be a more important project and deserving of attention first. The scheme to combine the Bureau of Mines and the Geological Survey might be found advisable later, but an overlapping of the work of these two offices is not of sufficient moment urgently to require attention.

DISCUSSION

A Call to Arms

The Editor:

Sir—If you would help to save our country from taking a perpendicular course straight down to hell, pull off your coat and jump to it right now. There are several million people in the United States ready to help in this job, and several thousand in foreign countries who will gladly come home and help to muck out the dirty filth of politics which is scattered in heaps all over the country.

This is the idea. In your paper from cover to cover, and in the heaviest black type, advocate the organization of a Non-Partisan Party and place at the head of it Herbert Hoover. Let your motto be: "Our government must be run by the people, and not by a few professional politicians." Ring out the motto in clarion tones across and up and down the land, and let it be known that such a party stands for honest government and will not be dominated by the stench of dirty politics as has been done in the past by both the great parties. Make it an open season on every kind of a politician, regardless of creed, color or age, in any place or spot from Town Constable up to Governor, from representatives in State legislatures, to members of Congress and the Senate.

It certainly is high time something was done when two handfuls of grafting party politicians can force down our throats any candidate for President they may desire, and then make us like it, just as has been done at Chicago and will be done again at San Francisco.

The only remedy is for the people to refuse to jump at the crack of the political whips and follow a selected leader like a flock of sheep. They must organize a Non-Partisan Party, for elective offices, use lawyers very sparingly, but lots of business men, accountants, engineers, mechanics, doctors, and hard-headed farmers with or without whiskers. Then there would be a show to run our government on a business basis and put a stop to political graft, which, at the present time, is without end and growing worse all the time.

There must be a change in our political system very soon and thinking people are demanding it. If this is not forthcoming, for the sake of decency, let us throw a heavy mantle over the statute of Liberty so she cannot see us as we go gaily sliding down the chutes to hell.

There, Mr. Editor, I feel a little bit better after getting this load off my chest, but still feel a trifle sad. However, I know a friend who has some raw and fiery tequila with a kick to it like a mule, so I know I shall be singing like a mocking bird pretty soon, and by morning

I will be completely recovered and joyously looking forward to another Mexican revolution.

A. E. ZEH.

Cananea, Mexico.

Some Observations on Smelting

The Editor:

Sir—For the questionable enlightenment of 'H. H. S.' I wish to contribute some of my own thoughts on this topic. His letter in your issue of June 19 was a real treat.

First, smelting may be defined as a melting with chemical change producing liquids, separable by difference of specific gravity. Second, it is to be observed, even though high-grade material is added during converting, most of the matte is fed to the converter as a molten mass. In order to convert economically, a 40% to 50% matte is required. Smelting, instead of simple melting, must precede the converting; the progress of the ore being from the roaster to the reverberatory, then to the converter. The modern reverberatory is, as H. H. S. suggests, a "melter" since the furnace atmosphere is neutral, or reducing, instead of oxidizing, as I was taught by my good professor in days gone by.

The self-firing of reverberatories by blowing dry flotation concentrate through the tuyeres as a substitute for pulverized-coal firing sounds reasonable, as most roasters are self-firing. Others have anticipated the process. J. H. Klepinger and Peter Thill (or J. H. Klepinger and Archie Wheeler) all formerly with the old Boston and Montana Reduction Works, at Great Falls, Montana, have letters of patent covering the principle of calcine (or concentrate) and pulverized coal being blown separately into a reverberatory. To my knowledge no experiments were ever made with the process.

According to the present-day practice the heat of roasting finds a most important use, namely, in the drying of concentrate as it descends through the roaster. In this connection it should be observed that sometimes the heat of the burned sulphur must be supplemented by extraneous firing.

H. H. S. is normal. He seeks to accomplish an object with the least effort. In the problem under consideration, the aim is to produce copper direct from the ore. This has been the ambition of a host of men. E. D. Peters in his 'Practice of Copper Smelting' dwells on the attempts to produce copper direct from the blast-furnace, without converting. In recent time we have a twin converter affair that was predicted to have possibilities. As I understand it, one chamber smelts and the other converts.

For my part I see no way to eliminate the reverberatory, except to operate the converter semi-continuously instead of in batches like a concrete mixer. This is to utilize the surplus heat not necessary for liquidation to smelt the dried concentrate (or calcine) so added. The blister copper is to be drawn off from the bottom and the slag is to be poured off the top.

This process once started would complete the cycle of operation in the following order:

Drawing of copper.

Charging of materials.

Blowing for slag.

Pouring of slag—that is the surplus.

Blowing for copper.

On the other hand the usual process, self-primed or rather reverberatory-primed, would complete the cycle of operation in this order:

Charging of matte.

Blowing for slag.

Pouring of slag.

Blowing for copper.

Pouring of copper.

It matters not with which foot you start. Either will take you to the same destination. This process would resemble a blast-furnace and reverberatory practice in that the converter always contains molten material and differs from them in that the matte is not produced continuously. It differs from the ordinary converter practice in that the converter always contains molten material.

A Code of Ethics

The Editor:

Sir—The '14 points' of the Code of Ethics of the American Society of Mechanical Engineers appearing in your issue of June 19 and the editorial comment thereon in your issue of July 3 have interested me, as, I suppose, they have other members of the engineering profession. The Code of the Mechanical Engineers is identical with that prepared by the American Society of Civil Engineers, which was, I believe, the first among our engineering societies to go into competition with Moses. However, making codes, like the influenza, is infectious, so we may expect the epidemic to spread to a number, at least, of the other societies before it runs its course.

The objections raised in your editorial to specific provisions of the Code are well founded, but the more important question, in my opinion, is, why have a special code of professional ethics, or, in fact, any special code of ethics?

In the first place, what good does it do? The spirit behind these codes is doubtless excellent, but the ordinary upright member of the profession has always observed the spirit and will continue to do so, forgetting about the letter. The shyster in the engineering professions, where there is as yet no compulsion behind the adopted codes, will continue to disregard both spirit and letter whenever it appears to further his interests. In some of the other

professions, where there are various forms of compulsion behind the written or unwritten codes, the shyster keeps the letter and violates the spirit.

On the other hand all such codes are definitely harmful because they tend to perpetuate the outworn theory that certain classes of men are holier than the rest of humanity and that upon them special standards of conduct are obligatory. That this theory has a bad effect upon both the elect and the unregenerate does not require proof.

If an engineer violates the ordinary rules of public or private decency, throw him out of the Society, and, if it seems advisable, let the world know the reason why. It is not done now, to be sure, but no fancy Code of Ethics is going to make it any easier. If, on the other hand, he comports himself as any honest citizen should, leave him alone, or, if you must say something, tell him that the Society is proud of him.

The sooner engineers and other professional men forget about special codes of ethics and get back to the Golden Rule and the ideal of Service, the better it will be for them and for the world in general.

The Case Oil-Fired Assay-Furnace

The Editor:

Sir—I wish to comment on the criticism of my article on this subject.

Mr. Sherlock states that the turning of the front baffle so that the flame hits the broad side of it enables him to cupel with the door open. In previously trying this arrangement, I found that it took almost twice as long to complete the fusions as it did by the method described in my article. This was due to the smaller amount of fuel that could be fed into the furnace and secure perfect combustion. It is also evident that 33 cupellations would occupy only about 50% of the muffle-space even in the smaller sizes of Case furnaces. That comparatively small number of buttons may be satisfactorily cupelled with the muffle-door open, for they can be placed in the most advantageous parts of the muffle. However, not all assayers can afford to use only part of their equipment and very often the last row of cupels is only two or three inches from the front end of the muffle. Under this condition, cupelling with a door open is neither practicable nor possible regardless of any baffle arrangement.

Mr. Sherlock further states that the gas or fume entering the interior of the muffle through the cracks does not interfere. Oxygen is needed for cupellation and if the muffle is being continually filled with an inactive or reducing gas it is plain that the oxidizing atmosphere is partly or even entirely prevented from coming in contact with the molten buttons and so the cupellation is retarded, or ceases altogether.

The opening or lifting of the upper part of the boss—opening of slots in some types—increases the amount of air available for combustion. This increase varies, but it is about 10% of the amount of air passing through the burner. This extra amount of air is forced into the fur-

nance by the difference in weight of the air-columns outside and inside and by the vacuum created by the spray of oil and air entering into the furnace through a rather narrow opening. Any operator can satisfy himself in regard to the above statement by lifting the upper half of the boss and regulating the air, oil, and dampers so that only a small flame is visible above the top of the furnace, then replacing the upper half of the boss and noting the flame and smoke that presently appears just above the dampers.

I agree with P. L. Guppy on the desirability of a low-pressure air-flame for assay-work. There were no statements in my article which could have been construed as a criticism of the low-pressure air used in the Case furnace. That the mechanical arrangement of the various parts was not all that could be desired is best proved by the extensive modification of the new Case oil-fired assay-furnace.

Books Written in a Hurry

The Editor:

Sir—Looking over the latest publications for sale in a book-store in this city recently, I came across 'Herbert Hoover: The Man and His Work', by Vernon Kellogg, published in 1920 by D. Appleton & Co. of New York. As I have watched Mr. Hoover's progress since he was at Kalgoorlie, Western Australia, in 1900 or so, and really believe him to be the man most fitted for the Presidency of the United States, I became interested in this book, which, I believe is a reprint of a series of articles appearing in an Eastern magazine. I opened it at page 105, and read the following:

"His work took him back to Australia, the land of his first notable success, but this time into South Australia, instead of West Australia. Here he took personal charge of a large constructive undertaking in connection with the rehabilitation of the famous Broken Hill mines. These mines were in the inhospitable wastes of the Great Stony Desert, four or five hundred miles north of Adelaide, the port city. The living and working conditions on the desert were a little worse than awful, but by his technical and organizing ability he brought to life the two or three abandoned mines that constituted the Broken Hill properties, and adding to them some adjoining lower grade mines, converted the whole group from a state of great unrealized possibilities into one of highly profitable actualities.

"An important factor in this achievement was his origination and successful development of a process for extracting the zinc from ores that had already been treated for the other metals, and then cast aside as worthless residues. There were 14,000,000 tons of these residues on the Broken Hill dumps, and from them he derived large returns for the company that he had organized to purchase the property. He also introduced new metallurgical processes for the profitable handling of the low-grade sulphide ores that constituted most of the mineral

body of the mines. Indeed, this work in South Australia did much to help prove to him what has long been one of his cardinal beliefs, namely, that the safe backbone of mining lies in the handling of large bodies of low-grade ores. When such great orebodies are given the benefit of proper metallurgical processes, and large organizing and intelligent building up of extensive plants, mining leaves the realms of speculation and becomes a certain and stable business.

"All this successful work in South Australia occupied but seven months . . ."

'Ye Gods'! I ejaculated, and said to a person near-by that Hoover needed protection from his friends; also that the matter was a libel on Australians. I am certain that Hoover never read proof on this section of Kellogg's book, as he would not have permitted it to pass. The only way to criticize the matter is to analyze each sentence:

(1) Broken Hill is not in South Australia, but in New South Wales, although only a short distance over the border. Practically the only mining in South Australia is at Wallaroo and Moonta, and at Iron Knob, with the great lead smelter at Port Pirie; but Hoover had nothing to do with them. Adelaide is not the port city, it being 12 miles from its own port. Port Pirie is the outlet for the Broken Hill field.

(2) Although the Barrier (Broken Hill) is in an arid region, it is by no means an inhospitable waste; while the living and working conditions in a city of over 20,000 people were not "a little worse than awful". I have been there.

(3) Instead of there being a group of large mines contributing 10% of the world's lead, 5% of its silver, and 20% of its zinc (in concentrates), Mr. Kellogg would have us believe that there were only two or three abandoned mines on the Barrier, with goats browsing on the dumps. His admission of 14 million tons of residues does not point to two or three mines. Why, at that time I know that the South and Central mines were estimated to contain over 4,000,000 tons of ore; and ore that carries 15% lead, 8 oz. silver, and 10% zinc is by no means low-grade. The Broken Hill Proprietary had by that time paid about £8,000,000 in dividends.

I am not sure of the year in which Mr. Hoover was at Broken Hill, but it must have been about 1906, when the Zinc Corporation, which is the company referred to in this book, was trying new processes almost daily and spoiled the reputations of a number of reputable men for a time. The corporation was in sore straits, and became the current topic in Australian and London papers. Eventually, after getting more money in London, local advice and that of Theodore Hoover—Herbert's brother—and absorbing the South Blocks mine, the Corporation passed through its troubles, and is now one of the big operators at Broken Hill. This rehabilitation occupied a long period. I have never heard of Herbert Hoover being responsible for the development of any of the flotation processes in use there. The metallurgists whose names are best known in this connection are Potter,

Delprat, Bradford, Shellshear, Courtney, De Bavay, Hebbard, Horwood, and Lyster.

Anybody reading that "the safe backbone of mining lies in the handling of large bodies of low-grade ores", would think that this was something new, whereas in America and other countries such a theory has been in practice at many mines for many years, and Mr. Hoover expounded it in his 'Principles of Mining'. As you, Mr. Editor, have discussed mining as a speculation and as a stable business, I don't care to intrude.

After reading the quoted page I did not go further, but some time I may look at the section on Kalgoorlie, where I spent nearly 12 years, up to 1912; yet I am afraid I may be tempted to peruse that critically also. It is a pity that in his admiration for Mr. Hoover, Mr. Kellogg was not more careful, and that the former did not edit the matter before going to press. I am now curious to know what my friends in Australia will say; but I can guess.

M. W. VON BERNEWITZ.

San Francisco, June 17.

Recent Metallurgy at Trail, B. C.

The Editor:

Sir—Referring to the excellent article on this subject in your issue of June 12, by F. H. Mason, in which he makes note of the Dings magnetic separators: Mr. Mason has not made it clear as to the type of machine and operation. In fact it is a two-belt machine and not a one-belt machine as he states. It is also of the high-intensity type. This machine has to operate with an extremely large gap, because the magnets and belts cannot be submerged, consequently they have to use a high-intensity magnet to obtain sufficient pulling force to reach the material lying upon the belt and covered with water. Underneath the poles of this machine there is an intense boiling action, and the pyrrhotite, which is attracted to the poles, is washed by this boiling action, freeing itself from the blende.

In your issue of March 13 you have another excellent article on 'Magnetic Separation on Bismuth, Tin, and Tungsten in Tasmania'. The authors state, on page 380, in regard to the standard Wetherill separator, that "these machines are not suitable for slime; that is, a material passing through a 150-mesh sieve." Also, "For slimy ores a magnetic separator that will treat the wet material is required." This is practically my experience and opinion. Mr. Mason, however, has not pointed out that this new type B-W wet magnetic separator is separating a pulp ground to pass through a 100-mesh screen. All through 100-mesh screen necessarily means at least 75% through 200-mesh. Consequently they are making a separation which has before been considered impossible. At the same time wet separating eliminates dust and dirt and the usual trouble in a dry plant, and removes the objections stated above.

I have not exact information here regarding the present arrangement at Trail, but when there last, the roasted

and ground ore was fed first to six machines, making a lead-zinc concentrate, going directly to the Deister tables. There was a second battery of six machines, re-treating the re-ground magnetic portion. This was followed by a third set of five machines and a final step of one unit, making eighteen machines in all, for 600 tons capacity.

Milwaukee, June 24.

Safety in Underground Haulage

Some standard regulations governing the operations of underground haulage are included in a recent bulletin of the Colorado Bureau of Mines. Cars operated by hand should have a convenient handle so that it is unnecessary for the trammer to place his fingers inside or outside the car-body. Depending upon the system used, the capacity of a car should not be too great, nor should too many cars be hauled in one train. The body and running-gears of cars should be kept in good condition. Where necessary cars should be provided with adequate brakes so that the hazard offered by the grade of the tracks will be reasonably overcome. Grades should not be so steep that they offer danger from derailment of cars. Locomotives should be of an approved type with all necessary appliances for their safe operation. They should be provided with head-lights and gongs. Gasoline-locomotives should be used only by special written permission of the Commissioner of Mines. Locomotives should be kept in good condition. The following minimum clearance should be provided: between top of cars and back, two feet; between sides of car and timber or rock sides of haulage-way, six inches; between top of car and trolley, 18 inches. Where electric haulage is used, shaft-stations must be electrically lighted and haulage-ways should have electric-light bulbs at least every 200 ft. For animal-tramming a light must be carried on the first car of the trip or by the driver. For hand-tramming a light must be carried by the trammer or on front of car. Rails should be of such weight as to safely carry the maximum load that may be imposed at maximum speed. They should be firmly spiked, have suitable joint fastenings, and rest on a sufficient number of ties of adequate dimensions. Frogs and switches should be properly blocked on motor-haulage roads. The track should be properly aligned and free from high joints, broken rails, defective switches and frogs. Chute lips should not project more than three inches over the nearest side of the cars. Jumping moving cars and uncoupling cars moving at a speed exceeding four miles per hour should be prohibited. Cars without brakes should not be ridden on grades. Speed of trains should not be greater than the conditions of the track make safe—in no case over 15 miles per hour. Where mechanical haulage is used and there is not room to pass at all points, refuge or shelter places, affording space of at least two and one-half feet at each side between the widest portion of cars or train and walls, should be provided not more than 50 ft. apart. These places must be kept open and clear at all times.

Electrolytic Separation of Copper From a Copper-Cobalt-Nickel Matte

By R. G. KNICKERBOCKER

INTRODUCTION. This article describes the operation of the copper department of the plant of the Missouri Cobalt Co., at Fredericktown, Missouri, of which I had charge during the first half of 1919. It should be remembered that copper was a by-product, the principle object of the treatment being the production of a suitable solution of the nickel and cobalt from which the copper had been entirely removed. Accordingly there will be some departure from standard practice in the electrolytic precipitation of copper on account of this special application of the process. A statement of the peculiar conditions and the measures taken to improve the results should be valuable. In order to simplify the discussion it is divided into four parts, namely, (1) the quality of the products delivered to the copper department, (2) the leaching plant, (3) the electrolytic plant, and (4) the furnace-refinery. The accompanying general flow-sheet (Fig. 1) shows the relation of the copper department to the scheme of treatment.

PRODUCTS DELIVERED TO COPPER DEPARTMENT. The analysis of the anodes from No. 2 blast-furnace averaged 55% copper, 19% nickel, 6% cobalt, 9% sulphur, and 10% iron. In the preliminary testing it had been determined that successful electrolysis required the sulphur-content to be below 3% and the iron between 7 and 8%. It was, however, found impracticable to produce a matte with this combination of low sulphur and high iron, because of the formation of sows in the blast-furnace. I have known this furnace to be blown in and out five times in one month. We had to handle these high-sulphur (7 to 8%) anodes very carefully, as they are extremely brittle and even with care they would break upon being immersed in the warm electrolyte. The high iron-content was necessary to prevent loss of cobalt in the slag.

The first anodes were cast with the Walker side-lug for support in the cells, but the brittleness of the metal caused these lugs to crack and most of the anodes were without lugs by the time they reached the cell-room. Then we tried the wire-loop type, in which heavy loops of copper-wire are held in place by a slot in the anode-mold. The vertical lug that held this wire made a re-entrant angle with the body of the casting and 50% of the anodes cracked as shown in Fig. 2. The electrolyte entered this opening and dissolved the copper wire, thereby allowing the anode to drop to the bottom of the cell, where it would cut a hole in the lead lining. Later this re-entrant angle was filled with metal, giving an angle of approximately 45° with the body of the casting. The anode was also made thicker (2½ in. at the top to 1¾ in. at the bottom), and this type gave much better service.

The method of casting the anodes was crude, and a poor separation of matte from slag was made. No settler was used, the furnace being tapped into a 6-ft. launder that discharged direct into the anode-molds. A wooden rake served to fill the corners in the mold as well as to skim off the slag. More than a quarter of the anodes had to be cleaned by hand. Besides the slag that was left sticking on the outside, and which was easily removed, there was the slag mixed with the metal in the interior of the casting. This occluded slag caused surprising increases of voltage in the cell-room. Another bad feature of the slag was the warping of the anode caused by the difference in conductivity of the two sides. This gave an anode that would touch the cathodes when placed in the cell, causing short circuits. An oil-fired tilting barrel-type of ladle in conjunction with an anode-casting wheel, operated by hand, was tried, but did not prove a success.

The anode that gave the best results was light-gray and dense; it had a close structure and was without gas-holes. These anodes were also tough and corroded evenly in the cell in case they were free from slag. The North American Lead Co., which preceded the Missouri Cobalt Co., made an anode in a reverberatory furnace that was tough, white in color, and resembled soft steel in physical characteristics. This was due to the larger proportions of copper, cobalt, and nickel, with small amounts of iron and sulphur. This was the anode that the Missouri Cobalt test-work called for, but the blast-furnace department was unable to turn it out. Such an anode would have been easy to electrolyze.

The roasted and pulverized matte as delivered to the leaching plant, to be used for the making of the electrolyte solution, was not quite so variable in composition as the anodes, but in physical condition and quantity it varied even more. Twelve to 14 tons of this matte came daily from No. 1 blast-furnace. The residue from the leach, amounting to 9 or 10 tons, was sent to the No. 2 blast-furnace. The following are typical analyses:

	Sulphuric						
	Copper	acid	Cobalt	Nickel	Iron	Sulphur	Chlorine
	%	%	%	%	%	%	%
Roasted matte ...	20.0	..	2.0	8.0	10.0	4.0
Leached residue ..	12.0	..	1.8	7.6	11.0	4.2
Electrolyte	3.5	3.0	0.2	0.4	0.8	0.1	0.015

The leach was not made with the idea of a high extraction, but only for the purpose of supplying the electrolyte. If the roast was not carried to 4% sulphur or under, the cobalt sulphate seemed to act as a coagulator of the raw sulphides and this residue would set in the tank and would have to be taken out with pick and shovel. Even when the chemical conditions were ideal the residue could not be allowed to stand after the solu-

tion was decanted or it would cause similar trouble. Provided the roast analyzed below 3% sulphur and 10% iron, and would pass 20-mesh, we had little trouble in making the required 45 tons of 3.5% copper electrolyte from 12 to 14 tons of matte every 24 hours.

The acid used in the leaching plant was of ordinary commercial quality, 60°B., and gave no trouble from chemical impurities. The water used was of poor quality; it contained calcium and magnesium salts, which precipitated in the tanks and pipe-lines of our circulation system. Much time was lost in cleaning the pipe-lines. At the time I took charge there were no means for heating solutions in the storage-vats, and the difference in temperature of the cell-solution caused additional precipitation in the pipe-lines. Accordingly steam-coils were placed on the bottom of each vat and the solutions were kept at the same temperature throughout the plant. Similar crystals formed on the sides of the lead lining in the cells and were taken out in the sludge. The analysis of crystals obtained from sludge, in water-soluble metals, is as follows:

	%
Copper	4.86
Cobalt	1.88
Nickel	3.73

At one time the lead in the matte was recovered by a chloride leach and considerable salt was left lying on the ground outside the leaching plant. Whenever it rained this salt was washed into our sumps and contaminated the electrolyte with an overcharge of chlorine. This had a bad effect on the cathodes and at one time entirely stopped the production of starting-sheets.

THE LEACHING PLANT. A general plan of the plant is shown in Fig. 3. A cycle of operations was as follows: the tank first received the wash from the last previous charge. The solution contained 8% sulphuric acid and was between 80° and 90°C., having been heated by a steam agitator during the night. The matte was dumped into the vat while the steam agitator was operating under 90-lb. pressure. Three hours was required for introducing the matte, and the agitation was continued only a little longer. The electrolyte was then decanted or siphoned to the storage-vat. Wash-water was added to the residue, and agitated 30 minutes, the liquor then being siphoned into the next vat, preparatory to another cycle. The residue was dumped through the discharge-cock and laundered into a tub from which it was wheeled to No. 2 blast-furnace. Under normal conditions one vat per day was leached.

The vats were without lead lining, they had inferior pipe-fittings, and poor arrangements for dumping, and the work was hard on the men on account of the dripping. There was constant trouble.

THE ELECTROLYTIC PLANT. As shown in the plan, Fig. 4, there are four sub-divisions of the plant, namely: (1) starting-sheet division, (2) cathode division, (3) soft copper division, and (4) lead-cell division. The work of making starting-sheets was arranged as follows: two men spent 8 hours lifting the copper blanks from the cells and stripping off the sheets; they weighed and

counted them, and carried them to the trimming and hanging-table; one man painted the necessary blanks and a boy hung the new sheets during the day-time.

The anodes used in the starting-sheet cells were 8 in. longer than those in the regular cells. This was on account of the length of the copper blanks used. In fact, we found that, on continued use of these blanks with the shorter anodes, the high-acid electrolyte would layer very readily in the space just beneath the short anodes and would tend to dissolve rapidly that portion of the copper blank upon which no deposition was taking place.

The circulating solution for the starting-sheet rows was raised by an Antisell pump which gave excellent service. We frequently wished that the other four pumps for the regular rows were also of this type.

The quantity of acid in the electrolyte was determined by the foreman of the leaching plant, who, when I first went there, maintained the strength of the starting-sheet solution at 6% free acid. This was then thought necessary to produce good starting-sheets but it was subsequently shown that 3% acid would give a tougher product. When the change was made it was no longer necessary to return the solution, depleted in copper, to the leaching plant, and the result was the discontinuance of a troublesome pump and pipe-line. Under the old method of using 6% sulphuric acid, the electrolyte that went to the starting-sheet cells contained at least 2% iron in solution; the amount of ferric iron increased with the length of time that this electrolyte was used. The current efficiency among the starting-sheets in February 1918 under the old system was 84%. The time lost due to power-plant delays or shortages of anodes or of solution is not covered by this efficiency figure. The proportion of good sheets made under the old system averaged about 60%. This sheet was made in 24 hours and weighed about 4½ lb. Under the new system we used twice as many cells, but only stripped at 48-hour intervals, thereby making a sheet whose approximate weight was 8 to 10 pounds.

About March 15, the proportion of starting-sheet scrap increased rapidly, and owing to changes in the material coming to the electrolytic department a serious condition developed. By the first of April we were unable to make a single sheet. The average analysis of the solution that would not make starting-sheets follows: 6.5% acid, 3.0% copper, 2.0% iron, 0.025% chlorine. The composite analysis of the anodes in the cells at this time was 56.9% copper, 19.5% nickel, 5.5% cobalt, 2.5% lead, 9.3% iron, 7.0% sulphur.

The difficulty was that the starting-sheet would break upon being bent 180° in one direction. We tried every change possible, made solution from pure water instead of old wash-water, cleaned all the sumps, storage-vats pipe-lines, and other places of possible contamination but with no beneficial result. We then started a series of tests, the results of which are given below. The tests were conducted in a cell 20 by 15 by 15 in., with a solution temperature of 50°C. The current density was maintained at 10.

Test No. 1

To determine if the trouble was in the water used in the leaching plant.

	Voltage	Acid %	Copper %	Chlorine %	Iron %	Number of bends
Matte and distilled water.....	0.4-0.6	6.0	3.5	0.007	2.0	1
Matte and leach-plant solution	0.4-0.6	6.0	3.5	0.013	1.8	1

This seemed to prove that whatever the impurity in the electrolyte, it did not come from the water.

Test No. 2

	Voltage	Acid %	Copper %	Chlorine %	Iron %	Number of bends
Matte and leach-plant water.....	0.4-0.6	6.0	2.8	0.012	1.5	1
Copper sulphate and leach-water	0.3-0.4	6.2	3.4	1.8	11

In order to be sure that the anodes did not contain the impurity that was causing brittle sheets, we ran a comparative test on the regular anodes and some old ones that were left by the North American Lead Co. The temperature in these tests was approximately 45°C. The acid strength in both solutions was 6% and the copper 3%.

Test No. 5

	Voltage	Copper %	Cobalt %	Nickel %	Iron %	Sulphur %	Lead %	Number of bends
Regular anode	0.6-0.7	56.9	5.5	19.5	9.3	7.0	2.0	1
North American Lead anode	0.4-0.5	62.0	6.0	20.5	4.0	3.0	2.5	2

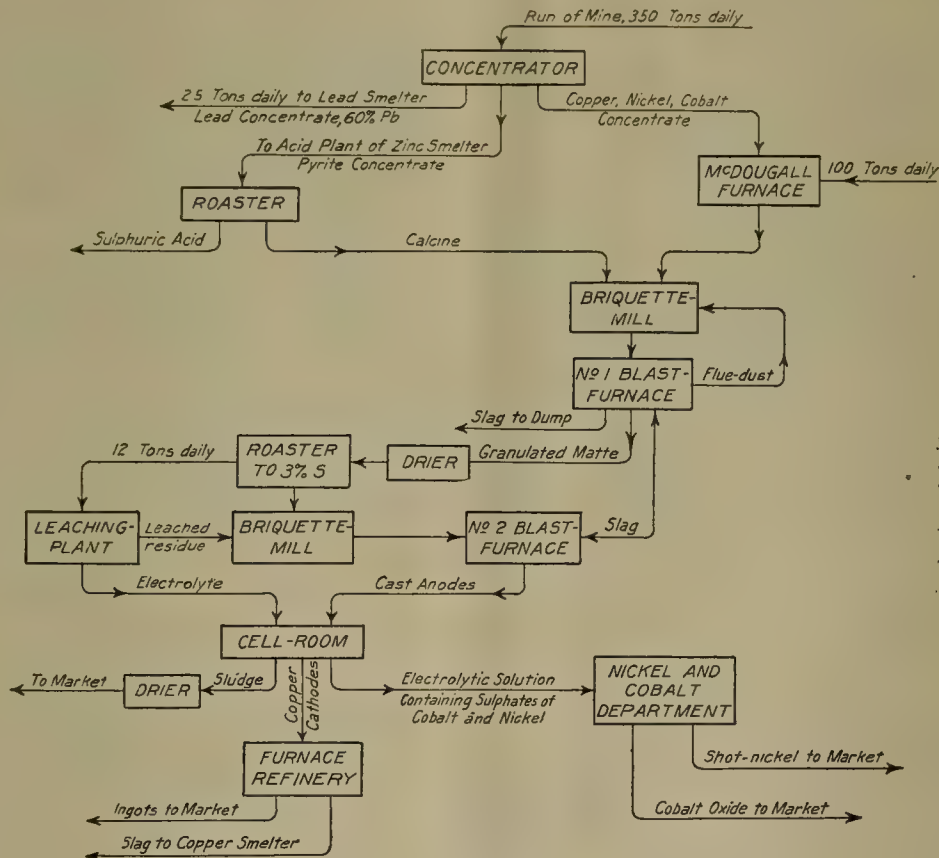

FIG. 1. FLOW-SHEET OF THE MISSOURI COBALT COMPANY'S PLANT

This showed that the water used in the leaching plant was all right, but that the impurity which caused the trouble either was in the matte or entered while the solution was being made up from the matte.

Tests with our leaching-plant acid and with C. P. acid gave us proof that there was nothing wrong with the former.

Test No. 3

The effect of reducing the strength of the free acid was learned

	Voltage	Acid %	Copper %	Chlorine %	Iron %	Number of bends
High acid	0.4-0.6	6.5	3.2	0.01	2.0	1
Low acid	0.8-0.7	2.0	3.0	0.01	2.4	4

Test No. 4

A small amount of glue was added to the electrolyte.

	Voltage	Acid %	Copper %	Chlorine %	Iron %	Number of bends
High acid plus glue.....	0.4-0.5	6.2	3.0	0.01	2.0	3
Low acid plus glue.....	0.8-0.9	2.3	3.0	0.01	1.0	7

Test No. 6

All conditions same as in Test 5, but glue was added to electrolyte.

	Copper %	Acid %	Number of bends
Regular anode	3.5	2.4	10-12
North American Lead anode.....	3.7	2.6	12-14

We decided to operate the leaching plant so as to produce an electrolyte with 3% acid and to add the solution-pocket of the head cell of each row half a pint of warm glue solution (25% glue) every eight hours. After making this change the following results were obtained in a 45-day period; blanks placed, 2936; good sheets stripped, 5543; sheets hung, 4346; weight of scrap and trimmings, 6881 lb.; weight of sheets, 24,379 lb. This shows 6% of the total number of sheets scrapped. The remedies for the production of brittle sheets may be summarized as follows:

(1) The spring rains had washed a large amount of salt refuse into the leaching-plant sumps and this was the probable cause of our difficulties. The figures given below seem to show that the troublesome impurities in our starting-sheets were metallic chlorides. An analysis

eral tests I used thinner paint than usual on the starting-sheet blanks and found that even under the worst conditions a somewhat tougher sheet resulted. It was decided that more care must be used by the painter in giving the blanks a uniform coating $\frac{1}{16}$ in. thick. The variation in thickness of this coat was sometimes due to a change in the viscosity of the oil. At times I have been convinced that some foreign impurity in the oil or graphite was causing part of our trouble, but I could find no proof. No more brittle starting-sheets, however, were produced after the acid was lowered to 3% and glue added. In connection with the character of the paint used, we found that it was impossible to make use of the standard paint (oil and lamp-black), as our voltage was so high that the copper burned through a thin paint and ruined the blanks for future use. Much thicker oil mixed with graphite was used as a coating and the oily graphitic surface was dusted over the flake-graphite.

The methods of hanging starting-sheets are given below in Fig. 5.

The following data are arranged to compare the work in the cathode-vats with that at Ajo as given by Henry A. Tobelmann and James A. Potter in Vol. LX of the Transactions of the A. I. M. & M. E.

of bad starting-sheets gave copper, 99.517%; chlorine 0.159; and insoluble, 0.144, as compared with 99.707%, 0.017, and 0.094 for the satisfactory sheets.

(2) The glue tended to overcome the activity of the impurities.

(3) The lower percentage of total iron obtained with the low-acid electrolyte, as well as the lower percentage of other impurities extracted gave beneficial results. Ferric iron decreased from as high as 0.5 to 0.1%.

The following data on current efficiencies are given by L. Addicks:

Ferric iron in electrolyte	Current efficiency
0.05	90.0
0.10	80.0
0.15	68.0
0.20	56.0
0.30	35.0

The electrolyte used by Mr. Addicks in this test was 5% acid, 2.5% iron, 3.0% copper, temperature 48°C.

	Ajo	Missouri Cobalt, average for 6 months	
Electrolytic, per minute, gal.....	1055	200

Ferric iron, effluent solution, %.....	0.94	0.60	0.16
Current density	7.80	10	10

FIG. 3. LEACHING PLANT

The low percentage of free acid permissible in our work was no doubt due to the soluble sulphates. The total of nickel, cobalt, and iron sulphates was at least 20%. The ampere efficiency was not affected by the lowering of the free acid.

(4) The use of thinner paint on the blanks. In sev-

Note. Chlorine in cathodes at Ajo, 0.05-0.35%.

In the operation of the cathode division, 14 men are employed on the day-shift and on each of the others the force consists of a foreman, one circulation-man, and one contact-man. At 7 a.m. the power is cut off for ten minutes to allow the vat-cleaning squad to cut out the ten cells that they are to clean in eight hours. The anodes and cathodes are removed from the two-head cells in the row to be cleaned, and are placed in racks in

soluble copper, cobalt, and nickel that could be extracted by a simple water-wash was determined by a series of tests supervised by J. A. T. Robertson, metallurgist for the company.

	Analysis of dry sludge %	Soluble in 5% acid %	Soluble in water %
Copper	51.35	1.24	0.50
Nickel	2.63	2.56	2.02
Cobalt	1.03	...	0.65
Iron	2.80	...

FIG. 4. VAT-HOUSE

order to prevent them from breaking or warping. The solution is then siphoned out of the cells and allowed to flow down onto the floor and thence to a sump. When this sump is full, the solution is pumped to a storage-vat. After the solution is out of the cell, one man, with

The acid does not give any better extraction of cobalt and nickel than water; moreover the acid-wash contains much iron. It would be possible to recover 9.25 lb. of cobalt and 31.15 lb. of nickel per ton of dry sludge by means of a water-wash. Valuing the cobalt at \$1 per

FIG. 5. HANGING STARTING-SHEETS

FIG. 6. AGITATORS

rubber boots and gloves, gets into the cell and scrapes the sludge through a 2-in. hole with a wooden shovel. Each cell has two of these holes plugged with lead stoppers having rubber washers. The sludge drops into a launder, which leads to a box where the excess solution is drained into the sump; the operator shovels it from this box into a wooden wheelbarrow and removes it to a wood-fired drying-pan. It takes 24 hours to dry two to three tons of sludge on this pan. The amount of water-

pound and nickel at 25c. per pound, a saving of at least \$17 per ton might be effected as well as a reduction in penalty of two units of cobalt and nickel. This had not been done up to the time I left the plant.

The men who cleaned the vats removed the 40-lb. cathodes and placed the starting-sheets and the new anodes that were required. They left 10 cells at 3 p.m. in first-class condition as far as electrolysis was concerned. Each vat was cleaned twice a month. If we

had been able to run continuously we would have made cathodes in 15 days and all 'pulling' of copper would have taken place when the vats were cleaned.

The head circulation-man's duty was to go over all solution-pipes from the feeders to the overflows into the pump-boxes in order to keep the rate of circulation at a maximum. The contact-man watched the voltages and corrected irregular readings by shining contacts, removing 'berries' and broken pieces of anodes or cathodes.

The handling of anodes in the cell-room was done by a small $\frac{1}{2}$ -ton crane with ordinary spider for moving anodes and cathodes.

Under the new scheme the 3%-acid electrolyte was passed through the head cells of the starting-sheet rows and flowed from there to the A, B, C, and D cells respectively.

Below are given typical analyses of the electrolyte as it flowed through the plant.

	Acid %	Copper %	Iron %
Effluent from leach-plant	2.8	3.5	1.0
From starting-sheet cells	3.0	3.1	1.2
A cells	3.2	2.7	1.39
B cells	3.7	1.9	1.52
C cells	4.0	0.07	1.73
D cells	5.1	0.016	2.0

The Antisdell pump lifting the starting-sheet solution could discharge into either No. 1 and No. 1A vat. The leveling-valve between the two was kept closed. The pump handling electrolyte for the four A rows discharged into 2A vat. The leveling-valve between No. 2A and No. 1B was left open. The A cells were fed from No. 1A vat. The solution was pumped back to No. 2A, leveled into No. 1B and the B cells were fed from No. 1B vat, pumped back into No. 2B, and leveled into 1C. The C cells were fed from No. 1C, pumped back into No. 2C, and leveled into No. 1D. The D cells were fed from No. 1D and pumped into No. 2D. The solution entering 2D was ready for the cobalt-nickel department.

The head cells of the C rows produced hard cathodes with a 3% acid electrolyte. The agitators used are shown in Fig. 6. These agitators reached below the anodes and cathodes, and the results obtained were highly satisfactory. The proportion of soft copper was reduced from 35% to 8%, and although the agitators required considerable attention this was more than offset by the reduced handling of soft copper. Soft copper was produced in the lower 18 cells.

To increase the amount of electrolyte in circulation and the period of contact of the electrolyte with the cathodes, pipes between the cells were replaced with open lead launders.

The following comparative data show the results from changes made in the lead-cell division.

	December 30 to April 1	April 1 to July 1
Acid in solution, %	6.4	4.0
Copper in solution sent to the nickel-cobalt department, %	0.04	0.01
Iron in solution sent to the nickel-cobalt department, %	4.3	2.0
Daily solution to nickel-cobalt department, tons.	10.0	20.0
Nickel in solution, %	0.7	1.2
Cobalt in solution, %	0.1	0.2

These changes in the quality of the products delivered to the nickel-cobalt department were due to additional

circulation, agitation, clean lead sheets, and vats free from sludge. The high-acid solution in these cells was hard on pumps. The D pump, for example, was repaired at least once every 24 hours.

From my experience in this plant, I suggest the following improvements:

- (1) The use of Antisdell pumps for handling electrolyte.
- (2) The use of solid bus-bars.
- (3) Protection of all wood vats and cells with anti-monial lead.
- (4) The washing of copper sludge for soluble metal.
- (5) The use of asphalt covering on cement floors and vat-bases where lead caps are not used.
- (6) The handling of sludge in lead-lined buggies from the discharge of the cells to the drying-pan.
- (7) Where circulation pipe-lines become clogged with crystals, the use of steam to keep all solutions at the same temperature. If this is not adequate the use of open launders, if possible.
- (8) The use of air-agitation and increased circulation in cells operating with electrolyte under 2% copper.
- (9) The use of insulators of the Ajo type on all lead anodes and cathodes.

FURNACE REFINERY. Up to January 1919, the company had not made any refined ingot copper. However, I started a small 10-ton furnace, which was a relic from the North American Lead Co.'s operations and a good furnace considering its size.

It was necessary to break-in an entire crew of furnace-men and ladlers. The only men that I had to draw from were farmers, whose lack of experience caused many expensive accidents before they became efficient. At first the furnace was equipped with oil-burners, but the use of oil, owing to the poor system of circulation, was expensive and gave poor results. Coal-firing, with a forced draft under the grate-bars, proved better. The copper was ladled with small 8-in. wrought-iron ladles requiring four men. It took about four hours to ladle six to eight tons of refined ingots.

The ingot copper, containing 0.02% nickel and 0.001% cobalt, was medium-grade casting copper assaying about 99.7%. The furnace operated only about 10 days per month, owing to the small production of electrolytic copper. During the first months the cost of brick and brick-laying amounted to one-third the cost of refining copper. For this reason, I discontinued the use of the smelter bricklayers and broke-in the furnace-men for this work with considerable saving. C. B. Underwood, who was then assistant superintendent of the furnace refinery, was responsible for a considerable reduction in the cost of the refining.

My opinion is that a metallurgical method is available for the profitable treatment of this ore. Frankly, I believe that the Missouri Cobalt Co. made the mistake of spending too much money and time on the extraction of nickel and cobalt, instead of first realizing on the copper and in the meantime working out, in a small test-plant, a scheme for the recovery of nickel and cobalt.

Early Days on the Rand

By J. E. CLENNELL

It was in the year 1854 that the earliest recorded discovery of gold was made in this district. In that year it was announced that one Jan Marais had made a find at the Yoke-Skey river, a tributary of the Crocodile, or Limpopo, and had also observed the precious metal on the Witwatersrand, the range of hills which forms the main watershed of the country. Some nuggets were exhibited at Potchefstroom, but there the matter seems to have dropped, for we hear no more of gold being sought for in this part of the Transvaal until 1883,

seldom remarkably rich. It was soon noted that these deposits were extensive, and that the gold was distributed in them with remarkable uniformity.

In November 1885 J. Bantjes began prospecting on the farm Roodepoort, and struck what was afterward known as the 'Main Reef', and in December Struben erected a 5-stamp mill, with which he and Bantjes crushed 50 tons of conglomerate in March 1886. The Main Reef was also uncovered by Walker on the farm Langlaagte and then Struben and Bantjes struck it again on Vogelstruisfon-

COMMISSIONER STREET, JOHANNESBURG

nearly 30 years later. In December of that year, Fred-eirk Struben noticed the gold-bearing formation of the Witwatersrand, and in January 1884, he began prospecting on the farm Sterkfontein. In April of the same year he was led to suspect the probable presence of gold-bearing conglomerate, from the occurrence of water-worn pebbles on the highest parts of the range, but it was not until September 1884 that a lode was struck east of Sterkfontein, assaying 913 oz. gold and 362 oz. silver per ton.

The conglomerate formation now known as 'banket' was first noticed in March 1885. The word 'banket' (pronounced bon-ket, with the accent on the second syllable) is the Dutch name for 'almond-rock', a sweetmeat to which the rock in question bears some resemblance. It consists of hard white round or oval pebbles imbedded in a friable darker matrix, which carries the bulk of the gold. The banket sometimes shows visible gold, but is

teins. These discoveries began now to attract attention, and many other persons started prospecting, some of them on the spot that became the site of Johannesburg.

In May 1886 Col. Ferreira informed the Government of the presence of gold on the Gatsrand, a parallel range of hills, south of the Witwatersrand. On July 18, nine adjoining properties were proclaimed by the Government as forming the Witwatersrand goldfield. About the same time the Ferreira and Natal camps, the nucleus of the present Johannesburg, began to spring up. The Main Reef was found to run through the ground occupied by Ferreira's camp; the houses were accordingly demolished and fresh building-sites sold to the inhabitants in what is now Johannesburg proper. On September 20, a plan of the new township was advertised by Captain Von Brandis, the Landdrost, or special magistrate appointed by the Government, and on December 8 of the same year the first sale of building-sites took place,

realizing £13,002. This may be considered to mark the foundation of the present city of Johannesburg.

The growth of the town from that date to the beginning of 1889 was probably without a parallel even among the annals of American and Australian mining settlements. At the time of my arrival, in March 1889, there were probably well over 20,000 inhabitants, whose dwellings of brick, iron, and wood extended over a mile from east to west and nearly as far from north to south. Little more than two years before, nothing would have been visible save a boundless expanse of green veldt, broken by ranges of rocky hills, with here and there a prospector's tent, or a few miserable hovels of unburnt brick, rudely covered with thatch, canvas, or a sheet of corrugated iron.

Every day saw coaches, mule-carts, ox-wagons crowded with newcomers, flocking in from all quarters. The older towns of Cape Colony and Natal, and also Kimberley, Barberton, and other once flourishing mining centres were being rapidly drained of their wealth and population to swell the ranks of the goldseekers on the Rand. The difficulty experienced by newcomers in getting sleeping accommodation was incredible. A night or two in a bullock-wagon or on a billiard-table was no infrequent experience, and there were many who gladly paid 35 or 40 shillings a week for a miserable truckle-bed in a tiny corrugated iron shed, with three or more others in similar plight for companions. Happy was he who, by a plentiful application of 'Keating', could secure immunity from the too-pointed attentions of the nimble tribe; and could also escape that other too frequent boarder who has won such renown in the recent war, and who has been aptly described as 'slow, but steady of purpose'.

In the outlying townships, such as Doornfontein, Jeppeshtown, and Booysen's, suburban villas with some pretensions to elegance and luxury were springing up, to form pleasant retreats for those who should win fortune in the great gamble. A splendid general view of Johannesburg could be obtained from any of the heights to the north and east, and a most impressive effect was produced by the immense variety of buildings with their metal roofs flashing in the sun, the spacious squares with scores of laden wagons, and along the southern edge of the town, the headgear of numerous shafts, the battery-sheds, workmen's and staff dwellings, stretching in a continuous line along the course of the Main Reef.

The life and activity of Johannesburg was mainly concentrated in the neighborhood of the market-square, which in a South African town fills the rôle of the plaza in Mexico and other Spanish-American countries. Running east and west, south of the square, was Commissioner street, the main thoroughfare, containing many of the principal stores, shops, and offices. The financial heart of the city, the Exchange, was accommodated in a somewhat imposing white stone building in a short street joining Commissioner street with the market-square, but much business was transacted in the open air 'between the chains' in front of this building, where an animated scene was generally to be witnessed as the excited crowd surged to and fro discussing the latest movement of

'Kaffirs', while from time to time a stentorian voice would make some modest announcement such as 'I'll sell 'Cities' at 15!'

To the east of the market-square, a large block of buildings with a façade of white stone housed the Post and Telegraph offices and other Government departments, which at that time were much under-staffed. The telegraph service was notoriously bad and important business with Capetown and Kimberley was frequently carried on by letter rather than risk a wire that might be cut at any moment by some enterprising speculator with reasons of his own for depriving the outside world of all knowledge of the existing condition of the market.

In the centre of the Square was a large red-brick market-house, in which the sale of fruit and vegetables was conducted at prices that (before the War) would have turned a London or New York fruiterer green with envy. Many large produce-stores surrounded the square.

Galvanized iron, that unsightly and uncomfortable building material, was everywhere much in evidence, but good building-stone had already been quarried at Doornfontein and a company had been formed for brick-making on a large scale. Masons and carpenters were paid 30 shillings per day, which in those happy days was looked upon as an extravagant wage.

Immediately before the date of my arrival, the Rand had experienced its first 'boom'. Speculation in stocks and shares presented far greater attractions than the legitimate development of the mines, and although many of the properties were already of proved merit, many others were placed on the market with nothing to recommend them except some attractive title, or the neighborhood of some well-known property.

Soon afterward metallurgical difficulties began to develop, and on reaching the pyritic ore it was found not only that the cost of crushing was increased but that the recovery of the gold by amalgamation was sadly diminished. Many croakers began to despair of the future of the goldfield and the inevitable 'slump' set in, which became acute in 1890. Many deserted the camp, and it was mainly the introduction of the cyanide process that saved the situation by solving the problem of treating the ore from the lower levels.

One of the chief difficulties with which this goldfield had to contend was the cost and delay of transport. The nearest point to which the railway extended was Ladysmith in Natal, some 250 miles from Johannesburg. Kimberley was about 300 miles away. An ox-wagon, with a load of ordinary merchandise, frequently took six weeks to perform the journey from the rail-head to Johannesburg. All heavy crushing machinery came from England or America, and as may be supposed, a long interval elapsed between an order and the delivery of the goods, though even in this respect, the Witwatersrand had an advantage over Barberton and other more remote districts. White labor at the mines received from £3 to £6 per week, while the Kaffirs got 10 to 15 shillings, and the cost of mining and milling was reckoned at considerably over £1 per ton.

Another advantage that the Rand enjoyed was the

presence of large deposits of coal close to the banket formation, at Boksburg, 12 miles east of Johannesburg, and at other points in the neighborhood. Many rich deposits in other parts of South Africa were unworkable for lack of fuel. The country round Kimberley had been denuded of trees to supply the wants of the diamond mines and in the rugged country about Barberton the transport of fuel was costly and difficult. A project was already on foot for building a light railway between Johannesburg and the coal mines. For political reasons, since the Boers dreaded the introduction of railways in the country, this line was always called the Rand Tramway.

The goldfield was further blessed with an abundant supply of water, since the Rand was the source of innumerable streams that go to swell the Vaal or the

The Main Reef Leader, a rich but narrow deposit parallel to and south of the Main Reef, had been struck on the City & Suburban property, just east of Johannesburg.

Situated at an elevation of nearly 6000 ft., with a fairly dry and bracing climate, with no great extremes of temperature, one would have expected to find Johannesburg a healthy spot. Nevertheless, a good deal of sickness prevailed, chiefly what was called 'camp fever', which was generally supposed to be a mild form of typhoid. The sanitary arrangements of the town were then, and for a long time afterward, in a disgraceful condition, and this, added to the frequent dust-storms of the dry winter, no doubt helped to spread disease.

Frosty nights and cold windy days were quite usual during the winter, say, from May to August, and in the

RANDFONTEIN CENTRAL MINE

Limpopo. In some instances the mine-water sufficed for milling purposes; in many places were *vleis*, or marshy ponds, which gave no abundant supply, and large dams had been constructed, notably at Knight's, later known as the Witwatersrand mine, to conserve the natural flow. On the other hand, there was not sufficient fall to admit of the utilization of water-power for mining or milling purposes.

Two small companies were working on alluvial gold, and a rich strike of ore, of a character somewhat different from that of the ordinary banket, had been made at the Black Reef, some eight miles south-west of Johannesburg.

The largest battery on the Rand at that time was that of the Witwatersrand company, which had 100 Sandycroft stamps, and a new 60-stamp mill, which was then considered a model of excellence and efficiency, had just been started at the Langlaagte Estate, erected by Fraser & Chalmers.

summer a short spell of heat would be followed inevitably by frequent and violent thunderstorms. These were sometimes preceded by squalls of wind that filled the air with red dust, giving for some time a fair imitation of a genuine London fog. The dust penetrated everything, so that all objects in-doors and out would assume a uniform reddish hue. It lay in drifts on the roads, filling the many holes and ditches. The effect after the heavy rain, which usually followed, may easily be imagined.

Life in the Johannesburg streets, especially at night, was not altogether without its excitements, although the 'tenderfoot' usually managed to acquire an exaggerated idea of the dangers awaiting him. At that time there were no street-lamps, but as there was usually a bar in full blaze at each of the four corners of every street-crossing; their absence was not such a serious inconvenience as might have been supposed. Burglaries and street robberies were not unknown, but in general the

streets were remarkably quiet, though no doubt many lively scenes were being enacted within the aforesaid bars. These establishments usually displayed the notice "All drinks sixpence except Three Star". Other liquors, however, were procurable, as the town had already been furnished with a good supply of water for domestic purposes.

Apart from the Stock Exchange and the bars, the chief place of entertainment was the race-course, within easy reach of the town, where the sport was carried on with much enthusiasm under the patronage of the Turf Club. North-east of the town the cricket-ground of the Wanderers' Club was a great attraction. Two theatres had already made their appearance; this, of course, was long before the days of the 'movie', but the 'variety shows' of the music-halls was a more popular form of entertainment than the 'legitimate' stage. Occasionally, however, a good theatrical company would visit Johannesburg, and full houses was the rule.

A project was on foot for establishing a free library and reading-room, and a number of clubs and masonic societies had their meeting-places. Churches had already been built for the following denominations: Church of England, Roman Catholic, Wesleyan, Baptist, Presbyterian, and Dutch Reformed. In the last the service was conducted in the Dutch language. Most of these churches had schools attached to them.

A hospital had been erected on the northern heights at a little distance from the town, on what became known as Hospital hill, but the accommodation was already insufficient and a new building was being planned, to be erected near the same site.

Four seemingly flourishing daily papers made their appearance, namely, the 'Transvaal Mining Argus', the 'Daily News', the 'Standard', and the 'Diggers' News'. The two latter became amalgamated. The 'Eastern Star' also rose every alternate day. These papers for the most part represented the interests of the 'Uitlander', or foreign settler, as opposed to the 'Afrikaner', or Boer element, between whom relations were none of the best already. The conservatism and primitive habits of the Boers provoked the ridicule of the newcomers, whereas the old established settlers, mainly of Dutch descent, were animated by a spirit of arrogance engendered by their apparently easy victory over the 'rooi-nek' in the war of 1880-'81. A great and not altogether unjustifiable opposition was displayed to the opening up of the natural resources of the country by hordes of not very desirable immigrants. Yet as many of these brought much money into the country, the Boers were not slow to reap what advantage they could, in the way of taxes and imposts of all kinds, and by heavy charges for transport and such agricultural supplies as the country afforded.

The old Boer transport rider, with his long train of oxen (eight or nine pairs in a span), his great slouch hat, and formidable whip, was a most picturesque object. A long iron chain connected the pole of the wagon with the foremost pair of oxen, the wooden yokes being affixed at intervals along this and secured to the necks of each

pair by loops of rope or leather. A small Kaffir boy—the 'voor-looper' guided the movements of the foremost animals, and kept watch over them, usually lying for hours face downward in the dust of the market-square, while his master haggled over the disposal of his produce.

The Kaffirs employed at the mines were of many different races, and tribal fights were by no means uncommon. I have myself witnessed several spirited combats of this kind. The opposing parties would establish themselves on neighboring mine-dumps, and after a prolonged period of mutual recrimination and vituperation, would make a simultaneous charge followed by a scrimmage in which 'knob-kerries' would crash unceasingly on unyielding craniums. Zulus, Basutos, Shangaans, Fingos, Matabele, and other tribes contributed their numbers to supply the unskilled labor of the goldfield, attracted by the hope of earning, in a few months, the means of providing themselves with such a supply of cattle and wives as would obviate the need for further work on the part of the lord and master. Needless to say, these dreams were not always realized, and many fell victims to drink, to insufficient shelter from the rigors of the climate on the high veldt, and to the many vices, and diseases that they acquired by contact with white 'civilization'.

THE ANAKIE SAPPHIRE FIELDS in Queensland had a profitable year during 1919. Never before has the price of gem stones risen so high, and never have so many buyers been doing business on the fields. While at the beginning of 1919 prices, generally speaking, were slightly higher than before the War, toward the middle of the year they steadily mounted, until the value of ordinary 'parcel' blues had, on the average, doubled. For large corundum, for which there was a keen demand during war time, the price has not varied much. It is said that in the present chaotic state of some European countries many people, having lost faith in paper money and scrip, are converting their assets into gems as having an international value. It is also stated that, since lapidarian workshops have been established in Great Britain during the War and the gem industry has assumed larger proportions in France, the cutting and distribution of sapphires is no longer, as it was, practically a monopoly of the towns of Idar and Oberstein, in Germany, and that consequent competition between old and new establishments tends to increase the demand and raise the price of rough stone. There has been a gradual rise in the price of stones since 1900.

GOLD has been found in the beds of rivers rising in the Carpathians, but they have as yet not been prospected. Particles of gold up to 2.35 carats have, however, often been found in the washings of the Oltul. In the district of Ramnicu-Valcea workings of an experimental nature were begun in 1912. The ore gives from 15 to 30 gm. of gold per ton, but the known reserve of this grade is only 3000 tons. These deposits present but a scientific interest, as yet no serious work having been undertaken to arrive at their practical importance.

Pulverized Coal in Metallurgical Furnaces at Cerro de Pasco

By OTIS L. McINTYRE

*The Cerro de Pasco Copper Corporation at La Fundicion, Peru, uses about 65,000 tons of coke per year, of which about 85% is local coke made at the smelter, and 15% is imported. This latter is very expensive, and of course both classes of coke enter largely into the smelting costs; consequently, about two years ago it was decided to determine what could be done in the way of using pulverized coal in the various departments of the smelter. The preliminary work consisted in determining the general combustibility of the local coals in pulverized form. These coals are obtained from two mines operated by the company and have the following general analysis:

Ash, 26.8%; volatile material, 40.05%; and fixed carbon, 33.15%.

This coal was dried by hand on steam hot-pans to less than 1% moisture, and then ground in a 4 by 4-ft. Marcy mill, the product being stored in barrels until a sufficient quantity had been pulverized to run a test. An average screen-test of this pulverized coal was about as follows: on 60 mesh, 8%; on 100 mesh, 8%; on 200 mesh, 14%; through 200 mesh, 70%.

The equipment used in the test is shown in Fig. 1-A. It consists of a coal-hopper, a 3-in. feed-screw driven by variable-speed motor, and a No. 2 Sturtevant blower supplying the air. The burner was a standard 6-in. pipe projecting about 12 in. into the furnace, which was approximately 4 by 4 by 16 ft. and constructed of firebrick. A number of tests were run with this equipment and though no pyrometric measurements were taken, observation of the furnace showed the results to be satisfactory.

The tests were first made with pure pulverized coal, and then with mixtures of coal and coke breeze, varying from 10 to 35% breeze, which gave practically the same results as did the pure coal. The lay-out was then changed, Fig. 1-B, to test the practicability of using more than one burner with a single feeder. This test was run with the 4-in. return pipe, first open and then closed, the results indicating that satisfactory operation could be obtained by either method with a properly proportioned system of pipes.

The next test made was in the sintering of fine ores on a standard Dwight-Lloyd sintering machine. These machines are oil-fired, and if coal could be substituted it would effect a considerable saving. The equipment used in this test was the same as shown in Fig. 1-A, except that a 1-in. screw-feeder, a smaller fan, and a 2-in. pipe burner were used. This test produced a satisfactory

sinter, though some trouble was encountered in the primary ignition of the coal, and the standard oil-muffle proved to be too small.

The next experiment was to test the feasibility of conveying pulverized coal under direct-air pressure. The lay-out used is shown in Fig. 2. Pulverized coal was placed in the pressure-tank and air at 20 to 25 lb. was then admitted through the $\frac{3}{4}$ -in. pipe at the top of the

FIG. 1. EQUIPMENT FOR PRELIMINARY COMBUSTION-TESTS FOR PULVERIZED COAL

tank. The 4-in. valve at the bottom was then opened and the coal passed through the 4-in. piping system to the coal-hopper. In this way 4000 lb. of coal was transported in from $1\frac{1}{2}$ to 2 minutes. The loss through the vent-pipe varied from 100 to 200 lb. This can be taken care of by using dust-collectors on the hopper, or an exhaust system which would return this waste coal to the main hopper.

The foregoing tests were so favorable that it was decided to erect a larger experimental pulverizing-plant. There were available for this purpose one set of 18 by 36-in. rolls, one 4 by 4-ft. Marcy mill, and two 6 by 4-ft.

*A paper presented before the American Society of Mechanical Engineers at St. Louis, in May 1920.

Allis-Chalmers ball-granulators. The drier consisted of five passes of 16-in. by 12-ft. screw-conveyor, mounted in a brick housing on top of the reverberatory flue, through which part of the flue-gases were by-passed.

After completing this plant it was decided to make the first experiment on the blast-furnaces, so No. 5 furnace was selected for the purpose and was equipped on one side only, as shown in Fig. 3. The coal was ground at the experimental plant and transferred to the No. 5 furnace in a hopper-bottomed car, being weighed in transit. A number of tests varying from 8 to 12 hours were run with this equipment. The air-pressure in the furnace averaged 34 oz., and auxiliary air for injecting coal about 22 lb. The charge of coke was reduced first 25% and then 50%. These tests were so encouraging that it was decided to equip the other side of the furnace with coal-feeders and run a test of several days' duration. This was done and the results were entirely satisfactory. During these tests the auxiliary air was taken from the converter air-line, which varied from 12 to 16 lb. pressure. The following quantities will give an idea of the proportion of coke and pulverized coal used:

Length of run, hours	14	50
Normal charge of coke, lb.	31,000	114,000
Actual charge of coke, lb.	17,000	61,800
Pulverized coal fed to furnace, lb.	8,900	41,000

The analysis and screen-tests of the coal used were practically the same as noted above. The performance of the furnace during all tests was carefully observed and was found to be fully equal to that when operating on the normal coke charge. Two difficulties were experienced on the blast-furnace test: namely, keeping some to the feeders in operation and keeping the tuyeres open. It was observed that in some of the feeders there was a slight back-pressure, due probably to partly blocked tuyeres. This did not affect materially the feeding, but forced some coal-dust into the feeder-bearings which mixed with the oil and finally bound the bearings so that it became necessary to shut-down that particular feeder and clean the bearings. This was easily done without stopping the other feeders, as the gears on the main shaft were mounted on feathers and provided with shifters. By using dust-proof bearings and a better-designed injector, we expect to eliminate this trouble.

Keeping the tuyeres open is absolutely essential to the safe and efficient operation of this process, and as it is a manual operation it must be handled by the operators. During these tests, tuyeres were 'punched' every 15 to 20 minutes on signal. On one occasion a tuyere became badly blocked, the feed was cut off and the tuyere-cap opened. The blast from the furnace blew out a dense cloud of coal-dust and molten material. The dust was ignited and burned on the outside of the furnace for 20 to 30 seconds with an intense flame about six feet long, the tuyere acting as an ordinary coal-burner. In view of the difficulty of keeping the tuyeres open and the connections air-tight, it is probable that the most satisfactory place to inject the coal into the furnace would be through a separate opening in the jackets, between and preferably somewhat above the tuyeres.

The No. 5 reverberatory was selected for the final test. All four reverberatory furnaces in use are identical: they are old-style, designed for hand-firing, and about 18 by 58 ft. inside the bridge-wall. The coal was discharged from the last mill into a hopper and dropped into a 7-in. pipe where it was picked up by an air-jet and conveyed to the coal-hopper, a distance of about 80 ft. with a rise of about 30 ft.; the top of the hopper was constructed similarly to a cyclone dust-collector. From the hopper a 6-in. variable-speed screw-feeder fed the coal into the suction side of a No. 9 Sturtevant Monogram blower; this in turn discharged the mixture of coal and air into the feed-piping from which branched five 6-in. pipe-burners into the furnace, the excess air and coal returning to the hopper.

The results of this test were disappointing, but when the following difficulties are corrected, the furnace will, beyond question, show a higher efficiency than the hand-fired furnace. First, the coal could not be dried sufficiently, the average moisture being in excess of 1.5%. This introduced difficulty in handling. The plant would not grind sufficient coal to the required fineness, the average screen analysis being: on 65 mesh, 22.8%; through 65 mesh, 8.5%; through 100 mesh, 25.6%; through 200 mesh, 42.4%.

Furthermore the discharge from the hopper to the feeder was too small, and the coal continually caked and bridged. The screw-feeder was so short that the coal flushed badly at times; also the discharge from the feeder was too far from the fan so that the coal accumulated in the suction-pipe and had to be removed with an air-jet. Under these conditions it was obvious that uniform feeding, which is essential to efficient operation, was impossible.

This test covered nine days, and was run for two days with the return-pipe open. Some time during the second day the return-pipe was blocked, due to overfeeding, and it was decided to continue the test without opening the run-pipe, the only difference being an apparently heavier feed at the burner farthest from the fan. With a properly designed piping system there seems to be no reason why a series of burners cannot be operated from a single feeder with or without a return. The last day's run of this test was made with a mixture of 75% coal and 25% coke breeze, which gave results equal to straight coal.

The following table shows a comparison between the average performance of reverberatories No. 2, 3, and 4, which were hand-fired, and No. 5 over the same period:

	—Average of—	
	2-3-4	5
Charge smelted per hour, tons.....	5.35	4.63
Coal used per hour, tons.....	2.00	1.99
Smelting ratio	2.67	2.33
Duration of run, hours	262	225
Time lost, hours	37

These results are really not so bad when the troubles experienced are considered and it is remembered that this furnace was not designed for pulverized coal, that it cools very rapidly during any shut-down, and that considerable time is required to bring it up to the smelting temperature again.

As accumulations of ash are an important factor in

FIG. 2. EQUIPMENT FOR TESTING FEASIBILITY OF CONVEYING PULVERIZED COAL BY DIRECT AIR-PRESSURE

FIG. 3. EXPERIMENTAL EQUIPMENT FOR USING PULVERIZED COAL ON NO. 5 BLAST-FURNACE

reverberatory smelting with pulverized coal, close observation was made of these accumulations, and the following samples were taken:

1. Ash and slag float on the bath: comes out when skimming in small and large pieces, sometimes has to be broken to pass the skimming-door, is easily handled when furnace is hot, but is tough and sticky when furnace is cool.
2. Ash in boiler cross-flue: spongy mass of ash and some slag accumulates in fairly large quantities in cross-flue between furnace and waste-heat boilers; is soft and easy to remove when first deposited, but if allowed to remain, is difficult to remove.
3. Ash on sides and roof of furnace: almost pure ash, lightweight and brittle when cold, appears to accumulate on sides and roof of furnace until too heavy to stick, when it drops and floats on the bath.
4. Ash in reverberatory flue, similar to No. 2.

Quite a large quantity of ash was deposited during each shift on the boiler-tubes, but was easily blown off by compressed air once or twice a shift. It was estimated that at least 50% of the total ash was disposed of in the manner described, while the remainder was deposited in the main flue and went up the stack.

As a result of these experiments a modern 250-ton coal-pulverizing plant was designed and is now in course of erection. Blast-furnaces, reverberatories, and sintering plant will be equipped for pulverized coal, and the experiments will be continued to ascertain the equipment most suitable for local conditions, which will then be used at the new smelter now being constructed. In conclusion, it may be of interest to note that these experiments and tests were carried out at an elevation of 14,200 feet.

THE Bering River and Matanuska coalfields in Alaska, according to a report of representatives from various government departments, contain high-grade bituminous coal much better than that on the Pacific seaboard, as well as some anthracite. The coal is closely folded and much broken, making it expensive to mine, and rendering it in part unavailable for present profitable exploitation. There are, however, in both fields, high-grade coal that can be mined and these will find an export market. Until they have been more thoroughly prospected by underground exploration, it is not possible to predict their annual tonnage. The committee says the development of Alaskan coalfields is of first importance, and recommends that it be encouraged by making the terms of leases as liberal as the law will allow; that underground explorations in the Matanuska coalfields be conducted with vigor by the Government; that companies engaged in prospecting the Bering River coalfield be encouraged to develop coal; that the departments give immediate consideration to the desirability of establishing a coaling-station for commercial and naval use at a port in the Aleutian Islands suitably situated to serve Trans-Pacific shipping; and that the Alaskan coal-leasing law be modified so as to allow a prospecting period of four years before a lease is signed.

The Las Chispas Mine, in Sonora, Mexico

By FERNANDO MONTIJO Jr.

The Las Chispas mine is near the town of Arizpe, and about 40 miles from the railroad at Nacozari, Sonora, by pack-trail through difficult broken country. There are several roughly parallel veins in the same spur of the Sierra, none of which, except Las Chispas, and Guillermo Tell, has been explored systematically.

Near the mine the surface shows old lavas, tuffs, and breccias, with an occasional patch of conglomerate. The Chispas vein occupies a fault-fissure that has a north-west-southeast strike. It has been explored by mine-workings through a number of layers of breccia and tuff, locally called *mantos*; these are closely related in mineral composition and about 600 ft. thick in all. Next the vein penetrates a light-gray dense rock, megascopically felsite-porphry, extrusive, followed by a pink felsite-porphry, together about 200 ft. thick. Then comes less than 100 ft. of No. 2 breccia, and No. 2 felsite, of unknown thickness and as yet unexplored except by a shaft outside the vein. These formations, throughout the length of the mine, occupy a gentle syncline.

A basaltic dike, dark-green, with numerous small crystals of pyrite, cuts nearly vertically, through the formations. This dike is anterior to the vein-fault. A number of minor cross-slips (crosswise in relation to the vein) and one major cross-fracture are posterior to the dike but anterior to the vein-fault. There is no evidence of further faulting posterior to the vein. The dike is first cut in cross-cut 619E (of the adit-level) at a distance of 110 ft. north-east of the vein. At station 627 it was found at a distance of 15 ft. from the vein. At station 629 the vein crosses the dike, both running together, however, for a distance of 35 ft. The angle between dike and vein at the point of crossing is about 11° . From here the dike is not again cut until station 648, beyond the largest cross-slip, is reached. Here vein and dike touch tangentially for about 40 ft. Finally, the dike is met 28 ft. south-west of the vein in the 650 or Dolores cross-cut. These relations are shown in Fig. 1. The vein-fissure is continuous throughout its explored length; the only effect the dike has upon it is to deflect its course at the crossing where both run together for 35 ft. and again where both touch tangentially for 40 ft. The dike is faulted by the small cross-slips, but not the vein.

The economic minerals are native silver, silver chloride and argentite mainly in the upper breccia; argentite, polybasite, stephanite, and ruby silver in the felsites below. Interior shafts extend into the lower breccia and No. 2 felsite, but outside the vein. At the 800-ft. or deepest level we are near the lower contact of the upper felsites, in the zone of secondary sulphides. Besides the silver sulphides, the ore contains pyrite and a very small quantity of zinc, lead, and copper sulphides, besides antimony, of course, in the polybasite and stephanite. The

gangue is quartz, clay, very little calcite, and fragments of country-rock. A typical analysis of shipping ore gives the following proportions of metals: silver, 350 oz. per ton; gold, 2.75 oz.; lead, 0.7%; copper, 0.2%; zinc, 1.4%; iron, 4.5%; lime, 1%.

Certain persistent habits of mineralization have been observed. The ore occurs along the vein in exceedingly irregular patches, or 'pockets'; these are irregular as to size, shape, position, and quality of ore. However, distinct shoots may be recognized with barren areas between them. These ore-shoots persist through the breccias into the felsites below, apparently with no change due to change of country-rock. The quartz filling is continuous in the fissure independent of sulphides. The dike also has no apparent influence on the mineralization. At the crossing of dike and vein there is no ore whatever, only fragments of dike and country-rock enclosed in clean quartz. At the point of tangential contact of dike and vein, the dike is again shattered, but, being along one of the recognized ore-shoots, there are sulphides with the quartz-enclosing fragments of rock. There is no ore in the cross-cuts reaching the dike, on either side. The vein cuts across the cross-slips at a constant angle of about 26° and in the areas of ore-shoots the ore invariably extends away from the vein for a few feet along the cross-slip. In the barren stretches there is no ore on the cross-slips. The 'caliche', or clay-filling, seems to play an important rôle in the mineralization. Usually the limits of an ore-pocket are defined by caliche completely filling the open spaces in the vein-fissure. Beyond the ore and caliche there may be up to a foot of open space between the quartz lining on either side but not an ounce of silver to the ton. The mineralizing solutions or emanations seem to have been confined within certain channels by the filling of caliche. A diagrammatic sketch of the conditions would be as in Fig. 2. The caliche is derived from the feldspar of the wall-rock. The feldspar phenocrysts of the felsite-porphry in the vicinity of the vein are so decomposed that they may be picked out of their molds with the point of a pin. Some of the caliche, however, is attrition gouge. The finding of caliche in mine-workings has always been taken as a sign of the proximity of rich ore.

The mine may be considered young, as measured by the extent of mining operations to date. Only two levels have been opened and not along the whole length of the vein, below the adit-level. Above there are four main levels, but the ore has not been stoped out altogether. The vein was reached near the north-western boundary by a cross-cut adit 1150 ft. long, continued by the main-level drift for 1250 ft. in a direction S. $42\frac{1}{2}^\circ$ E. to survey-station 629, or the point where the vein crosses the dike; then in a S. $34\frac{1}{2}^\circ$ E. direction to station 648, or the

point where the vein again encounters the dike and both touch tangentially, for a distance of 750 ft. Near this point a stringer branches out. Finally, from station 648 the main vein continues for 500 ft. more in a S. 54° E. direction to beyond station 654. From the cross-cut adit in the opposite, or north-west, direction there are further-

division there are three roughly defined ore-shoots: the first is between stations 610 and 615 and has yielded only second-class or mill ore, in small quantities; the second shoot, at the No. 1 interior shaft, has produced some first-class ore in stopes immediately below the adit-level and has not yet been mined out completely. It has not been

FIG. 3-B. 738 STOPE

GEOLOGY OF THE LAS CHISPAS MINE

more 520 ft. of drift. All these general directions between like points are the same on all levels above and below. There are thus four main divisions separated in a vertical plane by imaginary lines pitching 79° S. In the first division, north of the cross-cut adit there has been no ore found with the exception of a small and unimportant pocket cut by the Locarno shaft. In the second

found above the adit-level. The third and last shoot of the second division contains the discovery ore-pocket, which extends irregularly for about 150 ft. along the strike and which from near the surface to the 400-ft. level yielded several million ounces of silver. This is in the region of Las Chispas shaft. From the 400 to the 600-ft. level there is a break in the shoot, there being

practically no ore, but below the 600-ft. level the No. 2 shaft shoot appears to be the continuation of the Chispas shoot. The stopes reached from No. 2 shaft have yielded well and are not yet worked out, but the shaft has had to be abandoned and the ore will have to be reached from No. 1 shaft. The third division includes the most important part of the mine; within this there are two sub-shoots: the 38-39 shoot and the 43 shoot continue to the 800-ft. or deepest present level with no sign of discontinuity below 800 ft. as far as is ascertainable. No. 3 interior shaft is in the region of 43 shoot. The fourth and last main division contains the Tajo Chico called the 53 shoot below the main level and practically continuous with the 56 shoot, and, finally, the rather small pocket, but one that yielded very rich ore, where No. 4 interior shaft was started from the main level. No continuation of this ore has been found in the level above nor in that below. The Central air-shaft is close to the Tajo Chico shoot and in this region on the old levels above there is known to be considerable ore. These levels may be recovered by re-timbering.

At present no work is being done except in the 38-39, the 43, and the 53-56 shoots in the 700 and 800-ft. levels. For the past eight months production has been well above normal and absolutely all the ore extracted has been from the felsite zone below the upper breccia. The richest ore is in 842A raise from the 800-ft. level on the 43 shoot. On the 800-ft. level itself ore has been developed for 135 ft. in the north drift from No. 3 shaft and the end of the shoot has not yet been reached. This length of drift in ore on the 800 compares well with the longest drifts in ore in the breccia zone of the upper levels, thus exploding the theory that there are no important orebodies below the breccia zone. On the 800 the vein averages $6\frac{1}{2}$ ft. in width and the ore from the north drift, after hand-sorting, has averaged as follows: first class, 20% of the total, 360 oz. silver; second class, 35% of the total, 55 oz.; and waste, 45%, with less than 3 oz. silver. The gold content is about $\frac{3}{4}$ of 1% of the silver. No stoping has been started from the 800 yet, but three raises have been just begun; one of which will connect with the 738 winze for ventilation. The three are in ore.

Mining methods will be described briefly: The wall-rock is firm throughout the mine and the vein nearly vertical. It is apparent that the best way of stoping would be to open a raise from one level to the next, and to underhand inclined slices into the raise, leaving open space above (see Fig. 3). This method would be splendid but for the fact that if the ore-patch is of the form shown in Fig. 3 (an actual stope), the preparation of openings through waste for the underhand-slicing method would cost considerably more than overhand-stoping on stulls, following the ore. One cannot know beforehand what the shape of the ore-pocket is going to be. Both underhand and overhand stoping are used as may be advisable, but in either case it has been found cheaper to extract all the waste instead of leaving it in the stopes on the necessary timbering. Timber is scarce, expensive, and of poor quality. Imported timber is not to be considered on account of the cost. Openings between levels are

started from both ends simultaneously, connection of raise and winze being made at about half-way. Many intermediate short drifts as well as intermediate blind raises, inclines, etc., are made for prospecting along signs of ore and to find the continuation of a known patch of ore. Almost no timbering is required except for shafts, chutes, and the stulls in raises and overhand stopes, necessary for convenience, but not to sustain the walls. All ore is trammed out through the adit-level. Four interior shafts serve this level, but at present only one, the No. 3, is working. Each car, after being filled, is marked with the number of the chute or face it comes from, in order to keep a record of the production of each pocket of ore. This record has proved serviceable in prospecting for new pockets and more dependable than hand-sampling of the faces and stopes. The kind and grade of ore demand quality rather than quantity of material extracted, and mining operations are devised accordingly. The present compressor plant suffices for only six machines, besides the interior hoist and the one pump in No. 3 shaft, and the small column-hoist for winzes. Hand-drilling is employed to supplement the machines. Driving, sinking, and raising are generally paid by the foot of advance; stoping by the day, with a premium for an extra footage of holes drilled.

This article will end with a few remarks on recent local history: Political disturbances have greatly handicapped operations since 1911, by interrupting transportation and withdrawing security against labor troubles. In 1917 the mine was confiscated by the local government and handed back when all the rich ore exposed had been extracted. This confiscation followed a strike and favored the strikers, who obtained all their demands, while the mine was not operated by the company. Since then, however, better guarantee has been obtained from the Government. One result of the confiscation was the necessity for considerable unprofitable development work in the years following. Moreover, a flood swept away the pump-station on the Sonora river, leaving the mill without water. The pump-line has not yet been repaired and rain and mine-water have been used in the mill. Rain-water is available in limited quantities during the summer. The mine makes enough water in three months to fill the reservoirs for a mill-run of 10 days. The mill has had five 10-day runs each year in the past two years, producing about 35 tons of concentrate of about 500-oz. grade per run; head, 45 oz.; concentration, 11:1. The tailing is being saved for re-treatment. From the above it will be clear that at present the business of the mine is to produce first-class ore. The small amount of mill-ore extracted is in connection with shipping ore, the rest being left in place.

SAFETY, sanitation, lighting, and ventilation underground should receive proper attention and supervision. Safety devices and proper directed safety supervision more than pay their cost in decreased loss of labor through lessened accidents and saving in compensation. At large mines a safety-engineer is as much a necessity as a mining engineer according to the Bureau of Mines.

Three Hours With the Democrats

By C. T. H.

The Convention was a wonderful thing for San Franciscans. For the first time in history, this great event, the selection of a candidate for the highest office in the land by one of the great political parties, has taken place west of the Rockies. We who, perforce, have had to behold similar events through the eyes of Samuel Blythe, or Irvin Cobb, have had an opportunity to get our impressions first hand. Accordingly, on the second day of this history-making event, we hied ourselves to San Francisco's Auditorium prepared to behold with awe the portentous deliberations, to listen with rapt attention to the greatest spellbinders from 48 States, and to follow the words of the keynoter as he "views with alarm", and "points with pride".

After passing successfully the phalanx of police officers, ticket-takers, sergeants-at-arms, and other lesser dignitaries, we were conducted to a seat in the gallery, where we settled ourselves as well as possible on our aerie perch, and looked around at the rapidly augmenting throng. There was a glittering colorful panorama spread before us. On the main floor were the special seats for the delegates, each State section duly marked with its name on a placard erected on a stand. The ladies with their gaily colored hats and gowns added a pleasing touch of brightness. At one end of the great hall was the semicircular platform where the elect of the elect were seated. A husky table in front was provided to sustain the whacks of the chairman's gavel, while a magnavox sound-amplifier suspended from the roof and connected with the speakers' rostrum looked for all the world like a set of covered launders in a cyanide plant distributing pulp to a battery of Dorr thickeners from a central point.

Back of the platform and just below the great pipe-organ was an oil portrait draped in flags purporting to represent the President; at least we cannot imagine who else it could have been. Whoever the artist was, he certainly took atrocious liberties with the physiognomy of the man who is trying to make the world safe for Democrats for another four years. There he was looking down upon his satellites with an expression at once sardonic and admonitory, his watchful eye upon all they do, assisted by a glittering array of cabinet ministers, and other Federal office-holders in the flesh, who, as they flutter to and fro upon the floor, occasionally glance toward the portrait of their titular over-lord, as if in search of commendation and encouragement.

To the left of the organ in the gallery was what is known as an augmented brass band; and it was some band. Its working pressure must have been 100 pounds or more, with the safety-valve in imminent danger of popping most of the time. It could play 'Dixie' and, perhaps, one or two other things as alternatives during off periods. Then there was a mixed quartette, fully

equipped with seven-passenger megaphones, through which the members shouted a medley of sounds, which were occasionally distinguishable above the band, the pipe-organ, and the cheering delegates. Below the platform, groaning beneath its weight of notables, were the press headquarters at which all sorts of special correspondents were busily grinding out the story of the convention by rounds for the edification of one hundred million free American citizens. Flags, and quantities of red, white, and blue bunting festooned the galleries, flanked by what might be called the 'house' banners of rival candidates.

It was 12:45 p.m. and the hour set for the beginning of hostilities was 1. Suddenly there was a commotion at the far end of the hall. Thousands of necks craned forward to see. "It is Bryan", said someone in an awesome whisper. The band played 'Dixie' and everybody yelled. It wasn't Bryan after all. It was just somebody or other with a bald head. The crowd sighed with disappointment and resumed their seats. A diversion was created by a quartette, this time unmixed, that essayed to shout a song about Palmer, the "peepul's choice", to the tune of 'John Brown's Body'. A rival quartette struck up something about Cox and his supreme qualifications for the presidency, and nearly drowned out the Palmer quartette until the band played 'Dixie', everybody yelled, and all were smothered. To show that they were not down-hearted, the Cox people, bearing banners proclaiming they were Cox's army, stamped around the aisles yelling themselves hoarse, accompanied by boos and catcalls from the camps of rival candidates. A shrill crowing that sounded like McAdoodle-doo showed political bias in favor of the present dynasty on the part of a sizable group of lusty-lunged patriots. Oh, yes, the band played 'Dixie', and everybody yelled.

Finally, at 2, a tall, imposing, bald-headed man approached the rostrum, and whacked the husky table with his gavel. He said something or other about the meeting coming to order, but it took a lot of whacks before the roar subsided, and the delegates and spectators quit shuffling their feet, and the band played, not 'Dixie', but the National Anthem. Then came the invocation by a bishop of one of the assorted churches selected for the task. He prayed long and earnestly, for the United States of America, the President, his official family, the Justices of the Supreme Court, Senators, and Congressmen, in fact for everybody except Republicans. He expressed the hope that those in authority would administer their trust with skill and foresight, in which prayer everybody joined. At times when his vocal efforts coordinated perfectly with the magnavox, an effect was produced that was reminiscent of the renaissance of the

phonograph; in fact one could almost hear that nasal "Columbia-a-a Rec-ord", with which the first of the disc records were wont to conclude their offerings.

Another whack from the Chairman's gavel, and he read a telegram to be dispatched to the Governor of Tennessee commending him for calling a special session of the legislature to ratify the suffrage amendment. He asked a unanimous vote for authority to send the telegram in the name of the convention. He put the question, and got a bunch of ayes and a considerable sprinkling of noes. "Unanimously carried", he blandly announced. The steam-roller was on the job. Then came the report of the Credentials Committee. This promised to be interesting on account of the fight over the seating of Senator Reed of Missouri, who, though a Democrat, has been bucking the administration program at Washington. The secretary of the committee took his place on the rostrum, and read his report. He turned down Senator Reed cold. A spokesman from the Missouri section asked the privilege of the floor, and proceeded to the rostrum. He mildly objected to the action of the committee as over-riding the action of the voters in Senator Reed's district, especially as that district was almost 'chemically pure' Democrat, and rolled up whooping big majorities for the Party. The secretary, in reply, displayed a little more vigor, and after calling Senator Reed a renegade Democrat, and stating that he wasn't elected by anybody at all, and that he couldn't have no seat, nohow, he sat down, well satisfied. Another whack of the gavel, and the Chairman asked for the approval of the committee's report. Again came a lot of vociferous ayes, followed by some vigorous noes. "Unanimously carried", quoth the Chairman. The steam-roller was shooting on all six.

Then came the *pièce de resistance*. With solemn voice the Chairman delegated three notables to escort the permanent chairman to the platform. Three spotlights burst into view and focused their blinding rays upon the three escorts, as they wound their way around to where the great man sat, and trotted after him to the platform. He was Senator Robinson of Arkansas. With the assistance of the committee of three, he popped up through the trap door and landed safely on the platform. The Chairman whacked some more and introduced the permanent gavel-wielder. He was greeted with prolonged cheering, and the band played 'Dixie'. Then, when the noise subsided, he stepped up to the rostrum, and began his keynoting.

He singled out the Republican platform as the object of his scathing denunciation. He ripped it up. He tore it to pieces. He took it apart, plank by plank, and reduced it to kindling wood amid the howls of his delighted audience, who viewed the destruction of that cherished structure with vociferous glee. He lambasted the Republicans. He called them names. He heaped upon them vitriolic vituperation. What a bully time he had, and how they all enjoyed it. "Why", said he, in effect, "have the Republicans failed to observe their time-honored custom of declaring that a Democratic administra-

tion is always synonymous with hard times. Because", he paused with fine dramatic effect, "the American people are enjoying a period of prosperity unparalleled in the history of our country". "Gee", remarked a bystander, *sotto voce*, "I didn't know the Kaiser was a democrat and started the War to drive all the business to this country. Anyway," he philosophized, "if the Democrats are responsible for \$40 suits of clothes at \$100, and \$6 shoes at \$20, I'll be doggone if I don't vote for Harding." He got up and went out. So did we.

James M. Cox

The career of Governor James M. Cox, Democratic presidential nominee, began on a farm. He worked his way to be editorial writer for the Cincinnati 'Enquirer'; owner of the Dayton 'Daily News' and the Springfield 'Press-Republican', when he formed the News League of Ohio; and thence to politics, being a member of the Sixty-first and Sixty-second Congresses, and eventually becoming, in 1913, Governor of Ohio, which office he now holds. Cox was born on a farm near Jacksonburg, Butler county, Ohio, on March 31, 1870, the son of Gilbert and Eliza A. Cox. As a boy he learned to know what chores were early in the morning and late at night. As soon as he was able he spent more time at work than at play.

Cox as a boy attended country schools and later was graduated from the Middletown high-school. He always was earning money of his own by doing odd jobs. He was once a janitor in a rural church. Later he was a newsboy, working up to a printer on a Middletown weekly doing these things to help finance his way through school. He never attended college. After his graduation from school, Cox taught in rural schools for several years, but having a liking for the newspaper business he became a reporter on the Middletown 'News-Signal', then still owned by John Q. Baker, his brother-in-law, remaining there until he obtained a place on the Cincinnati 'Enquirer'.

Cox purchased the 'Daily News' at Dayton in 1898. The paper was at that time operating on a losing basis. However, he finally succeeded in making it yield a profit. Five years later he bought the Springfield 'Press-Republican', and today both newspapers are highly profitable institutions. He was elected to Congress in 1908 and re-elected in 1910. In this capacity he attracted the attention of State Democratic leaders, and in 1912, at the last nominating convention held in Ohio, became the party's candidate for Governor and won. His election in 1918 made him the only Democrat elected Governor three times in the normally Republican State of Ohio.

Governor Cox is a lover of the out-of-doors, plays golf, hunts and fishes, rides horseback, takes long hikes. He is stockily built, with a strong neck, indicative of combativeness, and has remarkable physical endurance. He is an eloquent campaign and after-dinner orator.

The Governor lives, when not at the executive home in Columbus, in a beautiful country home at Trail's End near Dayton.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

COPPER QUEEN FINDS WATER FOR NEW CONCENTRATOR.

BISBEE.—During the past year development has been conducted by the Copper Queen branch of the Phelps Dodge Corporation in the Cochise shaft in Warren, to get a substantial water supply for the new 4000-ton concentrator which is under construction. Within the last few days a strong flow of water has been met on the 1700-ft. level, about 400 ft. south-east of the shaft in the Black

ings. It is believed that good ore will be developed in the vicinity of the old works, and for the present mining operations in the new workings will be discontinued, and all efforts concentrated on opening up and re-timbering old drifts and stopes. Development work in the Nighthawk is progressing satisfactorily and it is expected that the main cross-cut on the 750-ft., or new, level should cut the ore with about 70 ft. more of work. It is stated that the orebody has been cut 30 ft. in one direction and 35 ft. in the other, with the faces of the drifts still in ore.

MILL AND MINE-SHAFTS OF THE MIAMI COPPER CO., ARIZONA

Rock section. So far the volume has not as yet been gauged, but it is believed that it will be more than sufficient for the needs of the mill. A conference of branch managers, assistant managers, and other officials of the Phelps Dodge Corporation was held at Bisbee. Conferences of a similar nature are called periodically by P. G. Beckett, general manager for the corporation, for the exchange of views and the discussion of matters of general interest. Among those who will be present are the managers and assistant managers of the Bisbee, Morenci, Tyrone, Nacozari, and Globe branches of the corporation; the superintendent of the Copper Queen reduction works, the general auditor, and all consulting engineers.

The Wolverine Mining Co. is planning a prospecting campaign in the neighborhood of old abandoned work-

Drifting is also in progress toward the Boras side-lines with 350 ft. still to go before reaching the fracture between the Boras and Nighthawk. It is believed that the Boras orebody extends to this fracture and therefore the prospects for opening good ore at this point are quite promising. A good body of ore was recently developed on the 600-ft. level. Ore is at present being shipped from the 500, 600, and 650-ft. levels. Mining operations are being conducted on a conservative basis to the end that future mining may be conducted as efficiently and profitably as possible.

JEROME.—Claud Ferguson of the Consolidated Arizona Smelting Co. is now in charge of the Planet mine. He is opening the old workings and finding favorable orebodies, preparatory to shipping ore to the smelter. It is rumored

that the California Southern railroad will join the Arizona Swansea and will then extend the latter railroad from Swansea around to the Planet mine. Several engineers have already been over the route, but no information is as yet obtainable as to when construction work will commence.

The Swansea mine is operating with two shifts at work in the mine and one shift running the mill, where it is stated a saving of 99% is being made. Eleven teams participated in the machine-drilling contest held at Jerome on the Fourth of July; four from the United Verde, four from the Extension, two from the Jerome Verde, and one from the Jerome Superior. There were six entries for the hand-drilling competition with double-jacks.

COLORADO

SHORTAGE OF LABOR IN CRIPPLE CREEK.

LEADVILLE.—Lead-silver ore assaying 38% lead and from 10 to 20 oz. silver has been opened up on the Chrysolite lease in a drift extended into virgin ground. The vein has been followed for 100 ft. and shows no sign of discontinuance. Two cars, about 60 tons, of zinc-silver ore were consigned to the A. V. smelter last week by Harry Schrader of Lake county, operating the Griffin property in the St. Kelvin district. The ore has an estimated value of \$30 per ton, and was mined from a vein averaging more than two feet wide that was recently opened in new territory.

High-grade ore averaging \$100 per ton is coming from rich streaks in a fissure vein under development in the Dinero tunnel in the Sugar Loaf district. Second-grade ore shipped to the A. V. Smelter brought \$40 per ton. Water is interfering with leasing operations on the Fanny Rawlins, and in excess of 100 tons of ore already broken will be delayed in shipment on that account. The ore contains gold, silver, and copper. Machinery has been installed and the shaft on the O'Donovan Rossa has been re-timbered and made safe to a depth of 523 ft. The old caved drift at this level has been opened for 200 ft., where work will now be started in expectation of opening an orebody dipping into the mine from adjacent workings.

GEORGETOWN.—Many old properties in the Georgetown-Empire district are resuming and, while production is at present light, development undertaken should bring more ore to the mills. The Seven Metals company is overhauling machinery at the Wilcox tunnel at Argentine, and work will be resumed after the holidays. H. M. Vincent has resumed on the East Argentine group owned by him and will shortly be shipping from a shoot of silver ore opened up before the property closed for the winter. Work is also to be resumed after the holidays in the Raymond tunnel, impending litigation having been satisfactorily settled. The Boston group in the Empire district is again active and development has been resumed by lessees. The Empress tunnel at North Empire is being re-timbered and placed in condition for development by the Randolph Gold Mining Company.

ASPEN.—An examination has recently been made of the properties of the Contact Mining Co. and Midnight Mining Co. in Queen's Gulch and Richmond hill and of the Fred Anderson group, in the Lake district of the Taylor river section, by mining engineers representing Eastern interests. The Fred Anderson group, if the report is favorable, will be purchased by the Cotoba company, controlled by Kansas City interests, and the Contact-Midnight properties by Pennsylvania investors. Construction of a mill is planned by the Hunter Park Mining, Milling & Leasing Co., and with a plant in operation large bodies of low-grade ore under development will be milled at the mine. The Little Annie mill of the Richmond Hill M. & M. Co. is to be increased to 50 tons capacity. Ore is broken in the mine and awaits alterations to the plant.

CRIPPLE CREEK.—Exploration on the 9th and 10th levels of the Rose Nicol mine adjoining the Portland estate on Battle mountain is being done by the Reva Gold Mining Co. that holds a long-time lease on the property. A drift and cross-cut is being carried on each level and, while the material in the drifts is low-grade, John Nicholls, the superintendent, expresses confidence in results. The diamond-drilling in the north-east end of the district is reported progressing, but beyond the fact that the drill is gaining depth no information of interest has been made public.

Sheriff Von Phul has leased the Jefferson mine dump on Gold hill. The mine, once a heavy producer of rich ore, has long been idle and the dump has never been worked over. Labor is scarcer than at any previous time in the district and, due to the cutting-off of the electric-car service, difficulty is experienced by miners in getting to work.

MICHIGAN

SHORTAGE OF COAL STILL THREATENS.

HOUGHTON.—Shortage of coal continues to dominate the mining situation. Bluntly stated, the Michigan copper mines have not coal enough to supply them for more than two months. That is the outside forecast. Quincy, the third largest of the Lake producers, has been operating on borrowed coal for a month. On June 23 it announced that it had a cargo afloat, but that it would have to pay back the greater portion of it to the Calumet & Hecla, so even this cargo does not help Quincy. Copper Range announces that it has coal on the way, a cargo being loaded on June 23 at a Lake Erie port. Without this it is doubtful if the Champion, Baltic, and Trimountain mines and the Copper Range railroad could continue to operate. Some of the smaller mines, notably Seneca, Mayflower, and Arcadian Consolidated, have supplies for two to three months.

Metal shipments from the Lake district have been almost negligible. Less than 1000 tons has been shipped in a fortnight by water. Calumet & Hecla is making rail shipments for foreign account. The company sold last week about 500,000 lb. to a European customer. It obtained fast delivery to seaboard on the Canadian Pacific.

A recent French order, said to have been 75,000 tons of copper, was not participated in to any great extent by Michigan mines. In fact foreign orders will not be a factor in this district till Germany begins buying. Germany formerly took as much as 36,000,000 lb. of Lake copper per month.

Committees are making preliminary arrangements for the entertainment of the American Institute of Mining and Metallurgical Engineers, which meets in the Lake Superior district in August. John Knox, underground-superintendent for the Calumet & Hecla, is chairman of the Copper Country committee, and with him is associat-

south, and west. White Pine is now employing 150 men and is producing 450 tons per day. This mine is badly handicapped by lack of labor. It could double its force in its present openings. While Michigan showed a production increase in May, as compared with April, it is badly hampered by labor shortage. Its drifts in the Butler lode cannot do justice to themselves with the present working force, which is half below normal. Victoria, free from coal worry, with its hydraulic-compressor plant to furnish power for all operations, cannot do itself justice because of its small force. It is the most isolated mine in the district and does not attract new men. Mass

THE BUTTE & SUPERIOR MINE

ed the alumni association of the Michigan College of Mines. Tentatively the program includes trips by automobile to the principal plants of the district, sessions at the College of Mines in Houghton, and social entertainment at the clubs and the college. The party comes to Houghton by boat and leaves by rail for the Michigan and Minnesota iron-districts.

Mining news centres around the small mines and prospects. The bigger companies are doing nothing in the way of construction or exploration, with the exception of the Calumet & Hecla's re-grinding plant for Tamarack sands, and the Quincy's new hoist at No. 2. The Stanton mines have abandoned temporarily large plans for metallurgical operations. Mayflower continues extensive exploratory and development operations with favorable indications appearing in each of the three directions, north,

copper is helping materially in keeping up the Victoria yield. Seneca continues as a producer from its original Seneca shaft and at the Gratiot shaft has definitely identified the Kearsarge lode. For this reason Gratiot development is being pushed.

MONTANA

NORTH BUTTE COMPANY IS CROSS-CUTTING ON THE 3600-FT. LEVEL.

BASIN.—The Ruby group of claims, which is now being worked by lessees, is to be developed by driving a cross-cut tunnel from the mill for a distance of 2500 ft. This will serve to tap the vein known to exist at the 800-ft. level. Plans also include modernizing and enlarging the 10-stamp mill now on the property.

ELLISTON.—The Silver Pick Mining Co. has resumed

further sinking operations on the Julia claim from the 350 to the 400-ft. level. The present owners have installed complete up-to-date equipment, which should prove adequate for several years active work. Smelter assays show 63 oz. silver, $4\frac{1}{2}\%$ copper, \$11 gold, and 10% lead. Charles Riley is in charge of operations, on which 16 men are being employed.

BUTTE.—The North Butte Mining Co. reports satisfactory development on the 3200 and 3400-ft. levels of the Speculator mine. The orebody on these levels shows no diminution either in size or in copper content. On the 3400-ft. level this orebody averages more than 4% copper. Cross-cutting is now being undertaken on the 3600-ft. level in the direction of the orebody. The production costs continue to hover around 14c. per pound.

CLARK'S FORK.—A 16-in. vein of bornite has been uncovered on the Clagy-Verdun property at a vertical depth of 30 ft. Work on the property was started only recently. Owners of the Mike Horse mines, on the North Fork of the Blackfoot river, report that satisfactory development work is in progress. No. 3 tunnel is now 800 ft. long. One vein of milling ore has been cut by this tunnel. No. 1 tunnel exposed a 6-ft. vein of good ore. In No. 2 orebodies from 6 to 12 ft. wide have been exposed in three stopes. Archie McDonald is resident manager.

NEVADA

BULLION SHIPMENTS FROM TONOPAH.

GOLDFIELD.—The north drift from the west cross-cut on the seventh level of the Florence is 220 ft. long and that to the south is 170 ft. long. These drifts, 726 ft. from the shaft, are in a vein 20 to 25 ft. wide. They have been driven on the foot-wall and two raises have been driven short distances from them. Two cross-cuts have been started to the hanging wall and it is planned to sink a winze. The vein is a promising body of quartz and E. A. Byler, engineer for the company, says the possibilities have not been exhausted and that work will continue until at least one winze has been sunk. There are several other wide veins in the west cross-cut and if the work being done fails to open ore, as appears probable, these will be prospected. A short branch from the south-east cross-cut has connected with the Aurelia lease-shaft after a fight with caving ground that lasted two months. This connection is for air and the shaft is being cleared. The cross-cut is being continued from where the branch was started. The objective, a point under an outcrop, thought to mark the southern extension of the Jumbo vein, is 300 ft. distant. A small quantity of ore has been sent to the Development mill from the Cracker Jack lease, but an important shipment has not been made from the Florence since April. The Florence management has two objects in the present work: to prospect veins west of the shaft and parallel to the main ore-channel, and to search for the main ore-channel south-east of the shaft. Maps show this ore-channel to extend through the Consolidated and Florence at a constant distance from the supposed Columbia Mountain fault, which in the southern part of the

Florence has been thought to turn east into the C. O. D. The strike of the outcrop, that is the objective of the south-east cross-cut, indicates a possibility that after turning east the fault again extends south. This fault was not recognized in the west cross-cut, but it is supposed to exist from the depth at which the latite is found east and west of it. Some engineers say this fault, which has been discussed for many years, does not exist. J. K. Turner, a Goldfield mining engineer, W. J. Tobin of Pioneer, and others are preparing to start work on patented claims owned by them near the Five to One tunnel. The tunnel, over 125 ft. long, is being advanced three feet daily. From the 125-ft. point it is lined with 6 by 8-in. timbers and 3 by 8-in. lagging. The present depth is 235 ft. and in 75 ft. more the greatest depth, over 300 ft., will be reached under the peak of the hill. The tunnel will be continued through the hill to determine if there is a vein. Rich pannings are secured and the work has attracted attention because success would mean the opening of ore more than two miles south of the Florence. Negotiations between the Consolidated and Jupiter companies indicate that the former is to build a plant and re-treat the mill tailing. The Jupiter owns one-third of the ground covered by the tailing, which is in places 16 ft. thick. It was reported several years ago that the tailing had an average value of \$4.10 per ton, but re-treatment in the mill, to which it was raised by a tramway that was costly to operate, did not give good results.

TONOPAH.—Ore 7 ft. wide and assaying \$40 to \$50 per ton has been opened by the Tonopah Extension in the Murray vein at a depth of 1760 ft., according to unofficial reports. The first mill clean-up in June was valued at \$49,000. The first clean-up of the Belmont mill in June gave 76,000 oz. of bullion worth \$83,600. The gross production during the first quarter was \$419,000. The operating expense was \$318,450. The Surf Inlet in British Columbia, a subsidiary, gave a profit of \$100,000.

DIVIDE.—Sinking of the Tonopah Divide shaft from the 800-ft. level has been started and will continue at a rate of three feet per day until the water-level is reached. This work, as usual, is being done with an auxiliary hoist.

BATTLE MOUNTAIN.—A carload of 100-oz. silver ore is being hauled from the Kattenhorn at Maysville for shipment. A number of lessees started work in the Kattenhorn last summer and since then irregular shipments of rich silver ore have been made. The mine contains many narrow shoots of high-grade ore, ideal for development by lessees. It was at one time under option to George Wingfield.

ARROWHEAD.—High-grade silver ore continues to be found in the Arrowhead shaft, now 270 ft. deep. Drifts will be driven at this depth. Ore 12 in. wide and assaying 200 oz. is exposed. A heavy flow indicates that the permanent water-level has been reached. The west drifts on the 100-ft. level and the intermediate level below continue to show 4-in. to 1-ft. widths of rich silver-gold ore, with 3 to 4 ft. of low-grade material.

MANHATTAN.—The ore on the 800-ft. level of the White Caps can be treated successfully by a process of flotation,

roasting, and cyanidation, according to the result of tests made for several months. The work on the 800-ft. level has been done east of the shaft and after the ore to the west and above the level has been tested it is planned to add a flotation plant to the present equipment.

UTAH

MINE-RESCUE AND FIRST-AID TEAMS ARE TRAINING FOR CONTEST IN DENVER.

SALT LAKE CITY.—Eight teams from Utah are expected to compete for the international championship in the first-aid and mine-rescue contest, to be held at Denver on September 9, 10, and 11, according to Dr. Arthur L. Murray, surgeon in charge of mine-rescue car No. 11, stationed in this city. Several years ago, a team from the Utah Fuel Co. won the world's first prize at San Francisco. The car of which Dr. Murray is in charge will be at the disposal of any crews wishing to train for the championship match during the entire month of August. The teams, which compete at Denver, will be made up of five men and a captain. Not more than one first-aid and one mine-rescue team may enter from any one mine, smelter, or mill; members of all teams must be bona fide employees. There is no limitation as to the number of teams which may enter from any State or district. The same team may enter for both mine-rescue and first-aid work. It is expected that teams from Park City, Eureka, Bingham, and from the coal mines in Carbon county will attend the contest.

Assessment of the metalliferous mines in the State, for taxation purposes, on the basis of three times the net proceeds, fell off \$29,295,402 in 1919 as compared with 1918, according to figures compiled by the State Board of Equalization, or a decrease of practically 50%. The assessed valuation of every other class of property in the State was increased, with the exception of water companies, but the increases were not sufficient to offset the reduction in revenue from the metalliferous mines. The real estate of metal mines, with the exception of ground owned for mills or townsite purposes, is assessed at a flat rate of \$5 per acre. During 1918, mining real estate was assessed at \$10,155,058, while during 1919 it was assessed at \$13,596,864. Improvement and machinery at the mines of the State was assessed at \$23,061,317 for 1919, as against \$22,877,982 for 1918.

BOXELDER COUNTY.—At the property of the Vipont Silver Mining Co., near the Utah-Idaho line, 90 men are now employed and shipments of silver concentrate are being hauled by truck to Oakley, Idaho, 25 miles distant. East of the Vipont properties, Tony Scoro and others are driving a tunnel, while to the west the Utah-Idaho Mining Co. is driving a cross-cut in the hope of reaching the same orebodies. At Rosette, it is reported that the Old Century and Suzanne properties will resume operations. At the property of the Salt Lake Copper Co. three lessees are now working. Seventeen miles north-east of Wendover, three small properties are operating at the south end of the Silver Island mountains.

ALTA.—Operations at the Cardiff property in Big Cottonwood canyon are being carried on at near capacity, and shipment of ore from the mine to the bins at South Fork has been started, the wagon-road now being in good condition. Fixe trucks are being used for ore-hauling, and a sixth kept in reserve. Forty men are now employed at the property, and this number will be increased.

At the annual meeting of the Big Cottonwood Coalition Mines Co., the following officers were elected for the ensuing year: W. G. Romney, president; E. J. Jeremy, vice-president; C. E. Robertson, secretary-treasurer; H. J. McKean, James A. Stanley, and W. H. Hurd, additional

MAP OF UTAH

directors. A new compressor was recently installed at the property. During the past year the company purchased a controlling interest in the Copper King Mining Co. Robert Gorkinski, mining engineer of Salt Lake City, has been engaged to make a complete survey of the company's claims for patent. During the past year the main adit was extended 926 ft., making the total length 2680 feet.

PARK CITY.—Shipments of ore for the week ending June 26 totalled 2234 tons, as against 1309 tons for the previous week. This increase was due to the removal of the embargo at the Murray smelter, to which most of the local mines ship their ore. The Silver King Coalition resumed shipments with the lifting of the embargo; this company not being permitted to ship any ore the previous week. The Judge M. & S. Co. shipped 796 tons; the Ontario, 718 tons; Silver King Coalition, 502 tons; and the

Daly-West, 228 tons. The Judge smelter shipped 108 tons of premium spelter during the week.

Larry Murphy and Malachi Maloney, miners, were severely injured in an accident in the Alliance tunnel, and have been taken to Salt Lake City for surgical treatment. The men, who were doing repair work, were injured when an empty car, which had been set on a side-track for their use, was hit by swaying cars of ore on the main line and tipped over on them. Both men were injured internally, and also sustained fractured arms.

EUREKA.—Charles Zabriskie, manager, states that two drifts are being driven at the property of the Lehi-Tintic company in the northern part of the district. Owing to shortage of power, there is but one shift being worked in each heading. The drift which is following the north-south break is reported to be in a promising formation. The other drift, which is being driven for the purpose of cutting the Gold Blossom vein, is passing through a hard formation, and no change is expected for the time being.

At the Copper Leaf property, in the eastern part of the district, but one drift, on the 1000-ft. level, is now being driven; work on the 1200-ft. level having been suspended for the time being. Officials of the company feel confident that as soon as the lime formation is reached the drift should enter more promising ground.

After sinking the Central Standard shaft to a depth of 490 ft., the work has been temporarily suspended in order that a reservoir may be cut on the 400-ft. level. This reservoir is needed to take care of water which was developed during the first 200 ft. of sinking; the reservoir which was cut in the porphyry formation not being satisfactory. John W. Taylor, manager, states that sinking of the shaft will be resumed shortly, and with the water properly taken care of, better headway will be made. The first 400 ft. was in porphyry formation, then about 40 ft. of shale was passed, while the last 50 ft. has been in decomposed lime, which carries iron.

Walter Fitch Jr., mine contractor of this district, has returned from Pennsylvania, where he has had an important contract in driving tunnels. Mr. Fitch brought with him a number of experienced tunneling men who will be employed in various pieces of work now under his direction in Utah and Nevada. Cecil Fitch, manager, states that a drift is advancing at a depth of 1750 ft. in the Plutus company's property. It is estimated that 200 ft. of drifting will be required to cut an important system of faulting, and officials of the company consider this the most promising piece of development that has been taken up in the Plutus ground. It is being done through the Chief Consolidated shaft. About a year ago, ore was encountered in the Plutus at a depth of 1000 ft., and since that time a winze has been sunk 750 ft., while considerable prospecting was also done on the 1400-ft. level.

BRITISH COLUMBIA

ROSSLAND MINES ARE TO BE RE-OPENED ACCORDING TO REPORTS.

NEW DENVER.—After much steady development, a substantial body of zinc-blende and galena ore has been cut

by a raise between No. 4 and No. 6 levels at the Bosun mine. This mine is being operated by the Surprise-Rosebery Mining Co., which owns also the Surprise mine, near Cody, and the Ivanhoe, near Sandon. The company has moved its offices to New Denver. Except for a few miners who are working on contract, the Standard mine, at Silverton, is being operated entirely by four groups of lessees, all of whom are doing well. Some unusually rich silver ore is being taken from the mine. Bodies of zinc-blende containing freibergite, granular chalcopryite, and occasional films of ruby silver have been found closely associated with the lenses and dikes of porphyry, which have intruded into the zone between the vein walls. The lessees are in communication with several smelting companies with the object of trying to get more satisfactory treatment-terms for this class of high-grade silver ore. Considerable adverse feeling has been aroused locally against the Silversmith Mines, Ltd., for its capitulation to the 'One Big Union'. The general opinion is that the members of this organization, who have done nothing for the workers and have been a considerable source of annoyance to the mine-owners, should be run out of the camp. The other mines in the district, while running an 'open shop', favor the International Mine Workers Union. When the O. B. U. called a strike many miners left the camp, and now are working at other camps, some at less than the Slocan scale of wages.

NELSON.—The Granite Poorman mine has been taken under lease and bond from the Vincent Development Co., of Walla Walla, Washington, by a recently organized syndicate. The Vincent company has had the property under option for some time, but concentrated its energies at the Eureka mine, where it did considerable underground development. It constructed a tramway, too, from the Eureka to the Granite-Poorman mill, and reconstructed the mill and added a flotation plant. The new syndicate will reap the advantage of all this work.

ALICE ARM.—The McLennan Silver Mines, Ltd., which recently acquired the Royal group, adjoining the Dolly Varden property on the west, has traced a vein for 400 ft. on the surface, which is believed to be an extension of the No. 4 Dolly Varden vein. The vein is 12 ft. wide, and samples taken from it have run up to 320 oz. silver per ton. A tunnel has been started on the vein, 600 ft. below the summit of the hog's back. A semi-Diesel compressor is being put in place at the North Star mine. The Dolly Varden is running at least one train per day and sometimes two. Each train carries about 90 tons of ore. The United Metals Co., Ltd., in the Alliance River district, has 20 pack-horses taking supplies into the mine and bringing ore to Alice Arm. Unless labor troubles break out afresh, there is every promise of a successful season in this district.

HAZELTON.—The Kitselas Mountain Copper Co.'s concentrator at Usk has been in operation since early in June. It is giving satisfactory results. A considerable quantity of ore is being treated and development is in progress at the mine. The ore carries gold, silver, and copper.

The Silver Standard mine has been shipping steadily this year and important development also is in progress. A new tunnel is being driven which has reached two veins and will continue until it cross-cuts the main lode. Transportation to the concentrator is furnished by a large motor-truck. It is used both summer and winter. Traveling in the winter is good after the snow becomes hardened, wires being wound about the truck wheels to ensure traction. Considerable high-grade ore is being shipped direct to the Trail smelter. Although the property is very promising it is yet in the development stage.

BARKERVILLE.—Placer miners are preparing for the season's work in the Cariboo district. John D. Galloway,

prosperity, which momentarily passed when the mines of the Consolidated Mining & Smelting Co. were practically closed down, would return is about to be justified. The company's mines, it is stated, are to be put on a producing basis very soon, it being expected that shipments will be resumed early in July. The ore-bunkers have been repaired; ore from the Mandy mine, Manitoba, which the management likes to handle with the Rossland mineral, is being received. There is still some question as to labor. If the men are available there is no doubt that the mines will be operated without delay and that Rossland once more will be active.

TRAIL.—Ore-receipts at the Trail smelter of the Con-

UNLOADING MACHINERY AT THE BRITANNIA WHARF, B. C.

government mining engineer, recently made a trip through a part of the section and, while it is impossible as yet to estimate the extent of the hydraulic mining to be undertaken, the prospect is good. Owing to the unusually late spring and the heavy fall of snow there should be a plentiful supply of water and late-fall operations appear assured. The old channel on Grouse creek, where the gravel is reported to be good, will be piped by the Waverly, and there will be operations at Lowhee and Stout's gulch. Generally it is expected that most of the old companies will be on their ground again and that some new leases will be worked. Notwithstanding lack of labor and high costs it looks as though the old Cariboo would see more placer mining, both hydraulic and individual, than it has for some years and that the gold output will increase.

ROSSLAND.—The faith of the old-time residents of Rossland, one of the oldest mining towns of the Province, that

consolidated Mining & Smelting Co. for the week ending June 14 totaled 6913 tons. For the week ending June 21 there was received 6742 tons. Two new shippers appeared in the latter list, namely, the old Whitewater mine, of Slocan, and the Sunnyside, Rock creek. The total ore receipts at the smelter for the year up to date are 135,068 tons.

PRINCETON.—W. P. Tierney, the contractor in charge of the construction of a railroad to connect the Copper Mountain mine of the Canada Copper Co. and the Kettle Valley railway, has stated that rails will be laid within 30 days. This 15-mile stretch of steel probably represents the hardest and roughest piece of construction undertaken in western Canada in recent years. The only work comparable to it is the road to the Dolly Varden mine. The contractor states that the cost totals \$1,500,000. He describes it as having been heavy rockwork, bridges, and trestles all the way.

ONTARIO

SUPREME COURT HANDS DOWN DECISION IN UNION NATIONAL GAS SUIT.

TORONTO.—An important point in regard to the taxation by municipalities of oil and gas wells has been settled by a decision of the Supreme Court of Canada, in the case of the Union National Gas Co. v. the Township of Dover. The company appealed against the assessment by the Township of the income from two producing oil-gas wells at \$62,376, being the amount of the returns for the year, less operating costs. The company claimed the right to deduct from the income, in addition to operating expenses, a deficit for the preceding year, and expenses for dry holes or unproductive wells, and rentals paid for oil and gas leases. The case was appealed from one tribunal to another, the original assessment being confirmed at every step, and the decision is again upheld by the Supreme Court of Canada, holding that the company could not make any deductions except for operating expenses.

KIRKLAND LAKE.—The Lake Shore produced \$41,187 during May from the treatment of 1636 tons of ore with an average recovery of \$25.18 per ton. Most of the ore now being milled comes from development work, but little being taken from the large orebodies blocked out. The management has decided to sink the shaft to the 800-ft. level. At the Harvey Kirkland two more veins have been uncovered. Stripping is actively in progress. A survey party is at work on the line of the Canadian Light Railways Ltd., which will run from Swastika through the producing area of Kirkland Lake and the new properties in Lebel township to the Larder Lake district.

GOWGANDA.—Additional rich discoveries are reported on the Castle property of the Trethewey. The vein recently cut on the shore of the lake has been traced over the brow of the hill and close to the first shaft. A shaft is being sunk on it and at a depth of 20 ft. the vein is producing ore of excellent grade. A new vein has been found running directly under the office building. Four shipments in all have been made since operations were started and the company has a large supply of high-grade ore sacked ready for shipment.

BEAVER HOUSE LAKE.—The management of the Argonaut has decided to sink to a depth of 500 ft. A 12-drill compressor and high-speed electric hoist have been installed and plans for the construction of a large mill in the fall are being considered.

COBALT.—A decision has been handed down by the Supreme Court of Ontario in the dispute between the O'Brien and the La Rose companies, having to do with the correct location of the boundary between the O'Brien mine and the Violet property of the La Rose. The O'Brien is declared to be entitled to possession of all the territory lying west of a direct line running from No. 4 post of the Colonial mine to the Shaw, thence to the Earle property. The La Rose is enjoined from trespassing beyond that line and damages are awarded. Cyril W. Knight, assistant provincial geologist, has commenced

the work of making a re-survey of the geology of the Cobalt silver area. It is estimated that the Bureau of Mines will have the field-work completed by late fall. Silver production from Cobalt during the first half of 1920 amounted to approximately \$5,400,000, according to preliminary estimates. Cobalt metallics and cobalt oxides marketed as a by-product brought the total value up to about \$5,750,000. The decline as compared with a year ago amounts to about \$1,000,000.

The Victory Silver Mines has increased its capital from 500,000 shares of the par value of \$1 each, to 2,000,000 shares of similar par value. Plans are being made to commence mining operations. The Nipissing Mining Co. will disburse a 5% dividend, amounting to \$300,000, on July 20. Total dividends from the Nipissing during 1920 amount to \$1,200,000, while the aggregate since 1906 amounts to \$21,540,000. The company has 1,200,000 issued shares, distributed among 13,000 shareholders. Liquid assets, consisting of Canadian and United States war bonds, as well as cash, ore in transit, etc., amounts to slightly over \$5,000,000. Production continues at the rate of well over \$4,000,000 per year. A movement is under way with the object in view to induce the government of Ontario to set aside ten townships in Northern Ontario, the timber from which to be sold by tender and the proceeds to go toward the construction of a macadam road from North Bay to Cochrane, with branches to Porcupine and to Iroquois Falls, covering a total distance of about 300 miles at an estimated cost of \$3,000,000. This would connect the mining, lumbering, and agricultural districts of Temiskaming with Southern Ontario.

YUKON TERRITORY

DREDGING OPERATIONS COMMENCE.

WHITE HORSE.—The North West Corporation has assembled its dredge on Claim 20, Dominion creek. The dredge was hauled from the upper Hunker river during the winter. The corporation has secured a second dredge which will be worked on lower Dominion creek, near Grenville. The Yukon Gold Co. has a dredge working on Gold Run and another on the lower Hunker. Three of the company's dredges are still idle. The White Pass boat 'Reliance' has loaded 800 tons of ore on the Kantishna river from the Tom Aitkin mine, for smelters in the South. The Yukon Silver Lead Mining Co. has shipped 30 tons of high-grade silver ore from Lookout Mountain, in the Mayo district. The Dominion government will erect a radio station at Mayo during this summer, so that the camp may not be so cut off during the long winters. The mail of June 1—the first in six weeks from the Mayo camp—brought 120 applications for mining claims from that district. The greatest prospecting activity was at Keno Hill and Lookout Mountain. Dr. Cockfield who is in charge of the Geological Survey field-work in this district, has arrived at White Horse. He is accompanied by T. F. Armstrong, W. G. Cuttle, C. A. Merriitt, and A. E. Pattison. The party will outfit at Dawson and then take the field.

COURT GIVES MINER JUDGMENT FOR \$500,000

The United States Circuit Court of Appeals has awarded John Tuppolo possession of Alaskan mining claims valued at more than \$500,000, property that heretofore had been claimed by the Chichagoff Mining Co. Tuppolo, in 1914, became joint owner with the Chichagoff company of four valuable claims near Sitka. In order to gain complete possession, avers Tuppolo, the mining company brought suit against him, charging insanity, had Tuppolo tried and sentenced to an asylum. Later the claims were sold by a guardian for \$1000. Subsequently Tuppolo brought suit in the Alaska court and was defeated. His victory yesterday gives him possession of two claims and one-half interest in the claims held by the Chichagoff company. An accounting of all profits since 1914 also is ordered to be made to Tuppolo.

ALASKA

Anchorage.—Good reports come from the Willow Creek district on the government railroad less than 50 miles from here. Willow Creek promises to become one of the heavy gold producers of the Territory.

Juneau.—The Alaska Treadwell Gold Mining Co. has taken a bond on twelve quartz claims on Nixon Fork on the Kuskokwim and is now busy prospecting the property. —The Independent Mining Co. reports the discovery of a rich orebody six feet wide at the end of a 109-ft. tunnel on its property at Windham Bay. —A contract for driving a tunnel 1000 ft. long has been let by the Admiralty Alaska Mining Co. which is operating at Funder Bay. —The Alaska Endicott Mining & Milling Co. has resumed operations at William Henry Bay where water-power is being developed for a saw-mill preparatory to the erection of a stamp-mill.

A syndicate has been formed at Juneau for the purpose of developing the Red Top group of claims on Bear Creek in the Portland Canal district. All the larger quartz mines of Alaska are operating full crews, and pre-war production has been resumed by the Alaska Treadwell, Alaska Juneau, Alaska Gastineau, Chichagoff, Kennecott, and Latouche companies.

Nome.—Regardless of almost prohibitive transportation costs, increased and renewed activity in placer mining is reported and no less than twenty big outfits are operating within fifteen miles of here. Extensive prospecting for oil is also reported.

Valdez.—The Columbia Red Metal Co. has resumed operations at Columbia Glacier near Valdez and is employing 50 men. A railroad carries ore from the mine to where it is loaded on steamers for shipment to an outside smelter. —The Valdez Gold Mining Co. has resumed operations and is assembling supplies and equipment necessary for driving a new tunnel.

ARIZONA

Jerome.—Smelter chemists have been taking samples of air around the reduction works at Clarkdale and Clemenceau for careful analysis of the foreign gases contained. This has followed an investigation by State bee experts, who have found a sickly condition prevalent among the bee colonies of the Verde valley, with the total loss of many hives. The

bee owners claim the trouble lies entirely with the smelter fumes. —There is local belief that the great orebodies of the camp are pitching toward Mexico under the Don Luis section, where exploration is finding new orebodies at comparatively shallow depth, though there is no expectation of striking continuations of the Bisbee lenses short of 2000 ft. The Boras mine has developed into a strong shipper and the adjoining Nighthawk is shipping about twenty carloads per month of 6½% ore from the 500, 600, and 650-ft. levels. A cross-cut now is being run on a new level at 750 feet.

Miami.—By cutting its dividend from \$6 to \$4 per annum the Inspiration Copper Co. has eliminated the necessity of drawing further from surplus. Present earnings cover dividends at the new rate of \$1 quarterly. The reduction will save \$2,363,934 in dividend outgo. Last year a deficit of \$2,905,174 resulted after paying the full year's dividends. Under the existing curtailment policy Inspiration's production costs have remained relatively high, the average being close to the 1919 figure of 13½c. per pound. Market conditions show no signs of material improvement in the near future and until the company's overhead can be apportioned over a greater production this cost cannot be materially reduced.

IDAHO

Coeur d'Alene.—The Caledonia Mining Co. will disburse a dividend of \$26,050 on July 5. This is at the rate of one cent per share. Quarterly payments hereafter will be at this rate. —The Bear Creek Mining Co. has shipped ore, its first carload of concentrate containing 61% lead and six ounces silver per ton. Shipments will be made at the rate of one carload per week.

Hailey.—The Silver Triumph Mining Co. has found a body of ore 6 to 15 ft. wide. One to two feet is galena rich in silver. The first samples assayed \$140 in silver and lead. The ore was disclosed in clearing an old cave, and has been found to a height of 70 ft. above the upper tunnel and its dip indicates that it can be found in a raise of 200 ft. from the main tunnel. Three parallel veins lie in a zone 100 ft. wide.

NEVADA

Pioneer.—The new winze on the 200-ft. level south of the main shaft of the Mayflower has cut a full face of mill ore, with a streak of high-grade in the hanging wall. Drifting for the Starlight vein is proceeding and is expected to reach the objective within 400 ft. W. J. Tobin, president, has gone to Denver to complete further financing of the corporation.

Winnemucca.—Unwatering of the Nevada Harmony, six miles east of Winnemucca, has been completed and mining resumed. With the present pumping outfit the management expects to keep the mine clear by pumping five hours per day. G. R. Williams is superintendent.

MEXICO

Pachuca.—The El Bordo shaft of the Compania de Santa Gertrudis, Mexico, which was partly destroyed by fire, has now been wholly repaired and the mine is producing about 600 tons per day. The Santa Gertrudis company is enlarging its mill from a capacity of 40,000 tons per month to approximately 60,000 tons.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. H. Shockley has been examining a mine at Auburn, California.

J. C. Pickering has opened an office as consulting mining engineer at Mexico City.

George A. Packard, of Boston, was in San Francisco last week, on his way to the Mother Lode.

E. F. Orr has resigned as superintendent for the Simon Silver Lead Mines Co., at Mina, Nevada.

Glenn L. Allen, mill superintendent for the Shattuck-Arizona Copper Co., is in San Francisco.

Roy Hatch, superintendent of the Alaska Gold Mines Co.'s mill at Juneau, Alaska, is at Salt Lake City.

A. E. Chodzko has closed his office in San Francisco, and is now at 1674 Long Beach avenue, Los Angeles.

Charles A. Mitke has spent a few weeks at Morenci on professional business for the Arizona Copper Co.

Rudolf Gahl, of Denver, is now with the Cerro de Pasco Copper Corporation, at 15 Broad Street, New York.

F. B. Kirkbride has been elected president of the S. K. F. Industries, to take the place of **B. G. Prytz**, who resigned.

John E. Bergh, of Salt Lake City, has gone to Chesaw, Washington, to start development on a gold prospect in that district.

Henry H. Holden, of San Diego, California, has been in the Payson district, Arizona, examining the properties of the Atlantis Mining Co.

Charles K. Barnes has been appointed to succeed **Morris P. Kirk** as general manager for the Yellow Pine Mining Co. at Good Springs, Nevada.

Solon Spiro, president of the Silver King Con. M. Co., at Park City, Utah, recently underwent a second operation in New York. He is reported as improving.

H. C. Plummer, formerly assistant superintendent of mines for the Cananea Con. Copper Co., has accepted the position of general superintendent for the Arizona Commercial Mining Co., at Globe.

Walter Lyman Brown, Director in Europe for the American Relief Association, arrived in New York on June 26 and will return to London immediately after planning winter relief operations with Mr. Hoover.

Albert Burch has resigned as manager for the Simon Silver Lead Mines Co., the Simon Sterling Mines Co., and the Simon Contact Mines Co., and, temporarily at least, is not acting as consulting engineer for any of these companies.

Oscar H. Hershey and **Lloyd C. White** will continue to act in a consulting capacity.

Utah, engaging in mining at Mercur, and in 1887 first became interested at Bingham, in property which later formed part of the Utah Copper Co. After selling the Brickyard mine at Mercur at a profit of \$60,000, he developed the Yampa mine at Bingham, which property he later sold to Moore & Schley for \$150,000, as against a cost to himself of \$40,000. He held to his faith in the copper-bearing porphyry of Bingham, and in 1895, Capt. J. R. DeLamar secured an interest in the property, and in December 1902, D. C. Jackling succeeded in getting the present officials of the Utah Copper Co. interested in the project. In January 1903, Col. Wall sold a half interest in the property to C. M. MacNeill, Spencer Penrose, and R. A. F. Penrose, for which he is said to have received \$420,000 and a 20% interest in

Col. Enos A. Wall

Obituary

Col. Enos Andrew Wall, one of the most prominent pioneer mining men of the West, died at his home in Salt Lake City on June 29. Death was due to a cancerous growth and came after a long illness. Col. Wall was born at Richmond, Indiana, June 21, 1839, the son of pioneers from North Carolina. After a common-school education, he came West in 1860, settling in Colorado. There he became interested in mining, and in 1863 went to Montana, where he continued his search for gold, but combined his activities as a miner with those of freighter and trader. In 1868 he went to Utah, remaining there for 14 years, after which he removed to Idaho, where he became superintendent for the Wood River Gold & Silver Mining Co. While in Idaho, he was elected to the upper house of the territorial legislature and served as president of that body. In 1885 he returned to

the stocks and bonds of the new company. In 1906 Col. Wall started injunction proceedings against the Utah Copper Co. when it was proposed to increase the capital stock to \$6,000,000 and to issue \$3,000,000 worth of convertible bonds, with the disposal of 51% of the stock to the Guggenheim interests. A restraining order was issued in this case, but later withdrawn. This was the beginning of a series of bitter legal battles between Col. Wall and the Utah Copper Co. over surface rights at Bingham. At the time of his death, Col. Wall owned approximately two-thirds of the outstanding shares of the Daly-West Mining Co. at Park City. On March 7, 1879, he married Miss Mary Mayer of Salt Lake City; this union being blessed with nine children, five of whom are living. Up to the time of his death, Col. Wall maintained an active interest in mining and Utah financial affairs, and was one of the wealthiest men in the State. He established and endowed the Wall Fellowship in Metallurgy at the Utah School of Mines at Salt Lake City. He was a man of great ability and enterprise, and kept abreast of the times in all the essentials and mining and metallurgy.

Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

July 5.—Copper is inactive but steady. Lead is quiet and firm. Zinc is dull but stronger.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

THE SHIPPING BILL

J. W. Powell, directing head of the Bethlehem Ship Building Corporation, Ltd., characterizes the Jones merchant marine bill as a highly constructive piece of legislation. He says:

"There has been a marked dropping-off of ship orders during the last six months, and a discreet carrying out of the spirit of its provisions should mean more contracts. The bill grants greater authority to the Shipping Board and permits it to put into effect various policies heretofore held in abeyance. Among these are a new sales program for the 10,000,000 gross tons of war-built, government-owned shipping. The Board is enabled to sell it at virtually whatever price it decides upon, with the proviso, however, that all ships, save those not needed for our own commerce, must be sold to American men or corporations.

"For ten years, owners of American shipping can deduct from their income-tax return, the net earnings of ships engaged in overseas trade, provided that the amount of exemption be applied, with an added amount to be decided upon by the Board, to new tonnage in American yards. New government construction of merchant ships is to cease, and an annual fund, for five years, of \$25,000,000 is to be created through the sale of vessels by the Board, with which to provide loans to individuals or private corporations engaged in shipbuilding for the postal service and the naval reserve. The postal authorities and Shipping Board are authorized to assist with adequate postal compensation to uphold such of our American trans-Atlantic companies which best serve the interests of American commerce. Marine insurance companies can amalgamate without fear of anti-trust laws. Bankers can do likewise for the creation of ship mortgages. To American ships is reserved the right of conveyance of all exports or imports which are granted preferential rates by American railroads."

THE MONEY MARKET

Increased discount rates can hardly be expected to do more than check further borrowing, according to the National Bank of Commerce, until the railroad situation improves so as to permit prompt liquidation of commercial and agricultural credits. In its money market discussion in the July number of its magazine, 'Commerce Monthly', the bank declares that the present partial breakdown of transportation, by interfering with the movement of products, has prevented the liquidation of a tremendous volume of credits such as is normally effected at this season of the year.

"During the period from May 18 to June 15, the money market has experienced continued tension which, largely as a consequence of the traffic situation, had become pronounced during the preceding month. The strain on credit facilities has been reflected in a further general advance in money rates. While some improvement of the traffic situation, mainly potential rather than actual, has been accomplished, it has not proceeded sufficiently to release and considerable part of the credit which had been locked up, and traffic conditions can be expected to improve only slowly. Meanwhile the credit requirements of a new crop movement will become pressing in the not distant future.

"Until the railroad situation improves sufficiently to afford an adequate physical basis for the prompt liquidation of commercial and agricultural credits, the increased discount rates of many of the Federal Reserve banks can hardly be expected to do more than check further borrowing; therefore, they should be a strong influence in effecting a curtailment of outstanding credit, in preparation for the heavy requirements of autumn."

MONEY AND EXCHANGE

		Foreign quotations on July 6 are as follows:
Sterling, dollars:	Cable	3.94½
	Demand	3.95½
Francs, cents:	Cable	8.70
	Demand	8.71
Lire, cents:	Cable	6.25
	Demand	6.25
Marks, cents		2.70

Eastern Metal Market

New York June 30.

The markets are inactive or only moderately active, depending on the metal. The vacation season is also having its effect.

Demand for copper is a little better and prices are fairly firm.

The tin market is quiet but moderately strong.

There is but little demand for lead but prices are very firm.

The market for zinc is lifeless. Prices are steady, however.

Antimony is quiet and steady.

IRON AND STEEL

After two days conference at Columbus, Ohio, the prospects Tuesday night were that a shut-down of union sheet and tin-plate mills on June 30 would be averted, says 'The Iron Age'. Amalgamated Association officers notified the various lodges to continue at work pending further negotiations, and it was expected that an agreement would be reached Wednesday. The sheet and tin-plate mills of the United States Steel Corporation, in which the open-shop policy prevails, are not affected by the Columbus negotiations.

The week has brought the steel-trade no relief from the distractions of its railroad entanglements. Operations continue at a fairly high rate, but with further additions to the unshipped stocks of finished product. Failure of coke supply has stopped a number of blast-furnaces, and in eastern Pennsylvania six have been thrown idle on this account or for repairs, and in the Chicago district, two.

Four inquiries from Western roads amount to 4750 cars, which will take 38,000 tons of plates, shapes, and bars. Eighty locomotives also will be ordered by two Chicago roads. The week's buying of cars by iron and steel and coal and coke companies has brought the total of such cars placed in June to about 6000.

COPPER

Sentiment may be pronounced a little better. This is probably due to improved demand for forward delivery, particularly last quarter. Sales of electrolytic have been made at the full price of 19c., New York, for delivery in, and through, the last quarter as well as for earlier positions, but demand is not heavy. There is also a heavier inquiry from foreign sources, England and the Continent, and substantial sales have resulted. Aside from these features basic conditions are unchanged, the industry being still more or less hampered by railroad and other troubles. The quotation of leading producers is firm at 19c., New York, for third quarter for both Lake and electrolytic copper. In the outside market varying quotations are obtainable as low as 18.25c., New York, for early delivery, but it is not believed that large quantities are involved. Exports of copper are on the increase, having been 39,415 tons in May. It is believed that for the first six months they will average 30,000 tons per month. In 1919 they were less than 1900 tons per month.

TIN

The market has been an uninteresting one with no pronounced tendency. For the greater part of the past week it has been dull with consumers manifesting little desire to buy. Most of the transactions have been among dealers. About 300 tons was sold last week up to Saturday on the New York Metal Exchange, 200 tons of this on Friday. It was all for future shipment in various positions at prices ranging from 45.75c. on Friday to 49.50c. last week Wednesday.

At the close of the week sellers were shy when demand was fairly good with 46.25c. paid on Friday and 47c. on Saturday. On both these days there were more buyers than sellers. This situation was also true early this week when 46.75c. was bid and 47c. asked for futures and 48.75c. bid and 49c. asked for spot. This bulge in spot tin over the future price is explained as probably due to a covering of short contracts for June delivery; when this is over, it is expected that the two prices will be more nearly on a level. Spot Straits yesterday was quoted in New York at 48.50c. per lb. and at £260 per ton in London. A week ago the London price was £270. Arrivals to date this month have been 3280 tons with 4195 tons afloat. Spot Straits continues scarce.

LEAD

The market is quiet but firm and featureless. It appears that consumers and buyers are comfortably supplied for their nearby needs and perhaps further ahead and hence manifest no interest in buying. Producers are believed to be catching up in production of the metal only slowly and hence are not pressing sales. As a result the market is stale and drifting. The leading interest's quotation is unchanged at 7.75c., St. Louis, or 8c., New York, for early delivery. That of the outside market is 8c., St. Louis, or 8.25c., New York.

ZINC

The market continues inactive and devoid of features. If anything, however, it is a little firmer than a week ago. Demand is still confined to intermittent orders which producers are filling at prevailing quotations. Prime Western for delivery in the third quarter is quoted at 7.55c., St. Louis, or 7.90c., New York.

ANTIMONY

This market is quiet with wholesale lots for early delivery quoted at 7.50 to 7.75c., New York, duty paid, depending on the grade.

ALUMINUM

Quotations for wholesale lots for early delivery are unchanged at 33c., New York, by the leading producer, with 31.50c. asked by other sellers.

ORES

Tungsten: In the absence of any domestic buying, even at lowered prices, it is reported that sales have been made for export at \$5.75 per unit. Some interest is awakened by these sales as well as considerable speculation.

Ferro-tungsten is unchanged at 85c. to \$1.15 per lb. of contained tungsten.

Molybdenum: Entire lack of interest characterizes this market and prices are nominal at 65 to 75c. per lb. of MoS in regular concentrate.

Manganese: There is not much demand just at present and quotations are a little easier. About the best price that buyers would pay at present is 70 to 75c. per unit for high grade ore for early delivery.

Manganese-Iron Alloys: Demand for ferro-manganese continues light. A sale of 185 tons for fairly early delivery at \$190, delivered, is reported, but special considerations are said to explain the low price. For last half the quotation of producers is regarded as firm at \$200, delivered, with \$225 asked for prompt. Some British alloy is available for shipment from August on at \$195, seaboard. More demand characterizes the spiegeleisen market, which is very firm at \$75, furnace, for all positions. There are domestic inquiries aggregating 1000 tons for fairly early delivery as well as one for 4000 tons for foreign shipment.

This Crew Is 100% Efficient

The men are of *uniform* strength. Any one of them can finish a job begun by any other.

This Crew Is Inefficient

It averages the same as that above, but the little fellow cannot finish the big man's job.

These Two Crews Show the Importance of Linde Uniformity

Any one of the millions of cylinders filled with Linde Oxygen must be interchangeable with any other produced by Linde.

For *uniformity* of oxygen is just as important to welders and cutters as is a high standard of quality.

Expert chemists are constantly at work in Linde laboratories to prevent the slightest deviation from the extreme high purity of Linde Oxygen.

Seventy-one Linde Distributing Stations make it possible to promptly supply welders and cutters everywhere with Linde Oxygen.

The Largest Producers of Oxygen in the World

T. A. RICKARD, . . . Editor

THE Missouri School of Mines and Metallurgy at Rolla has issued a booklet that contains the records of students and alumni who engaged in military service during the War. Of 273 American undergraduates enrolled, 207 entered the military service, and 23 others were in the Students Army Training Corps. Still others were engaged in work of production at which they were urged to remain in preference to enlisting. In all, 600 Missouri School of Mines men were in active service.

ON August 10 the Secretary of the Interior, Mr. John Barton Payne, will hear arguments in behalf of claimants under the War Minerals Relief Act in regard to questions under dispute with the Commission functioning under that Act. The hearing was granted at the request of the American Mining Congress, following the receipt of hundreds of letters on the subject. Arguments on the following points will be submitted: request and demand, purchase of property, net losses, and commercial importance. The status of the Commission and its method of procedure will also be discussed.

BY courtesy of the Director of the U. S. Bureau of Mines we are informed that the Secretary of the Interior has formally approved the transfer of the Mining Experiment Station that was established at Denver in 1910, and moved to Golden in 1917, to Reno. This station will be known henceforth as the Rare and Precious Metals Station and its work will be conducted in co-operation with the Mackay School of Mines of the University of Nevada, which is at Reno. This change seems, on the face of it, to be well considered; it will be a source of strength to the Nevada School of Mines, and also a matter of convenience to those in the field most likely to derive benefit from it.

NINETY mining companies, including practically all of the large producers of zinc and lead in the Tri-State district, which centres at Joplin, have agreed upon a plan of curtailment that is expected to force the price of 'ore' to \$60 per ton. The first step is a complete shut-down for two weeks during the early part of July. This is to be followed, so it is reported, by other periods of idleness, to the end that production may synchronize with demand and the price for the product may thereby be maintained at a higher level. While the operators point to the fact that their employees, who have worked steadily

for several years, should appreciate a short vacation, and that at any rate those who desire can work on the farms where there is an unfilled demand for help, we are somewhat skeptical as to the result of repeated unsought holidays on the attitude of the miners. There is the possibility that the employees may assist in the curtailment and make temporary shutting-down unnecessary by the simple expedient of 'tapering off' more frequently and persistently. They may reason that, since the demand for their labor is limited, the market can best be supported by a co-operative plan of curtailing the rate of production per man; and the operators would not have a particularly strong argument against such a policy.

AMONG the documents received by us recently is the annual report of President Butler on the work of Columbia University. Owing to our interest in that university and its distinguished head, we looked over the report, expecting to find something interesting. We did. Among the more prosaic items we note that full professors are now paid \$6000 to \$8000 per annum, "with the expectation of paying salaries of \$10,000 to a limited number of teachers of unusual distinction". We like the use of the word 'teacher' in this context; every professor is not a good teacher; a "teacher of unusual distinction" is worth his weight in gold to a university, and to a community. In 1919 the Carnegie Foundation paid \$60,000 to the Treasurer of Columbia University in retirement and disability allowances. Altogether the Foundation has given Columbia \$405,439 in 13 years. The President reviews the changes in the university's chief interest: for fifty years the centre of gravity lay in the classical languages and literatures. "It then moved, with results that were not entirely satisfactory, to the natural and experimental sciences. From these it moved to the field of social and political science, and there perhaps it rests at the present time, although in a state of unstable equilibrium." This is as noteworthy as it is satisfactory. The first purpose of the university is to produce good citizens, the highest type of citizenship. For such the scientific study of economics is imperative.

IN a report filed with the State Public Utilities Commission of Utah, which is investigating certain special contracts under the terms of which the Utah Copper Company purchases its electric power, Mr. John M. Hays, treasurer for the company, gives some interesting

data. The company has treated since 1907, when operation commenced, 75 million tons of ore from which was recovered one and a half billion pounds of copper, 416,000 ounces of gold, and 4,400,000 ounces of silver. The metal content of this ore averaged less than 1.5% copper. The company's property, which includes the Bingham & Garfield railroad, was appraised for taxation in 1919 at \$58,000,000, or practically 9% of the assessed valuation of all property in the State. From January 1, 1913, to January 1, 1920, the company purchased 900,853,060 kilowatt-hours of electric power, for which it paid \$4,034,426 to the Utah Power & Light Company. Indicative of the importance of the mining industry to Utah is the fact that of 72,740 wage-earners employed in the State in 1918, 22,022 or more than 30% were engaged in the mines, mills, and smelters. In 1917 the mines produced metal to the value of 99 millions, and in 1918 the output totaled 86 millions, while the ore hauled in that year accounted for 85% of the total tonnage handled by the railroads. While Utah has other natural resources, she certainly can ill afford to hamper the mining industry.

ANY machine whose motion is rotative has certain decided advantages over one of the reciprocating type. It has fewer bearings, it is more compact, weighs less, requires lighter foundations, demands less attention, and costs less than a reciprocating machine designed for the same work. Steam-turbines, turbo-compressors, and centrifugal pumps are built on the rotative principle and for many uses are rapidly displacing older machinery. In spite of the fact that centrifugal pumps rarely have an efficiency of more than 75% the other advantages are so great that their use in mines and mills is constantly becoming more general. For underground pumping, high-pressure multi-stage pumps are required, but these have been developed to such an extent that suitable equipment can be obtained for any service. Centrifugal pumps, however, are peculiar in that they work advantageously only under the conditions for which they are designed. The quantity lifted, the head pumped against, and the speed of operation, each must coincide closely with that for which the pump is built, if a reasonable efficiency is to be obtained. The principles on which the pump performs are unusual. We happen to remember a large and successful mill where a standing order directed the operators to open the valves in the discharge-line before starting centrifugal pumps on the theory that otherwise the motors would be subjected to extra strain when starting. As a matter of fact the shut-off load, as it is styled, when the discharge-line is closed is the minimum and the facts directly contradicted the theory on which the mill superintendent based his instructions. In this issue we publish an interesting and valuable article on centrifugal pumps by Robert S. Lewis, Professor of Mining in the School of Mines at the University of Utah.

IT is said of Jefferson that he did not think it ridiculous to state that were it left to him to decide whether they should have a government without newspapers or newspapers without a government he would not hesitate

a moment to prefer the latter. Mr. Bryan's proposal to establish a government newspaper, for the avowed purpose of giving reliable news, reminds us of this saying of the father of the Democratic party. We were glad that Mr. Bryan's proposal was defeated at the recent Convention, all the more as we had read of Secretary Daniels disembarking at San Francisco from a warship to the salute of seven guns and in the company of Mr. George Creel. If there be a *bête noire* to American journalism, it is Mr. Creel. To think of a government paper edited and controlled by him would provoke mingled derision and resentment. In truth, most of us are tired of bureaucratic interference with legitimate industry and to have the Fourth Estate subjected to the unintelligent tyranny of such a man as Creel is unthinkable. The defects of democratic government are obvious enough, and the only hope of amelioration lies in the criticism of a free press. Even the license of a string of disreputable papers, like Hearst's, is preferable to the subordination of journalism to a petty official at Washington. Sane criticism is the best cure for the ills of maladministration; upon the development of healthy public opinion rests the welfare of representative government in this, or any other, republic.

ELSEWHERE in this issue we publish a particularly valuable article by Mr. Gilbert Rigg, metallurgist for the Broken Hill Associated Smelters Proprietary, Ltd., describing recent improvements in lead smelting as practised at Port Pirie, South Australia. The smelting of galena ore in the blast-furnace, following a preliminary roast for the removal of part of the contained sulphur, is comparatively old, the principal advance during recent years being the development of blast-roasting. Although the early edition of Hoffman's standard treatise on the metallurgy of lead antedates the use of Huntington & Heberlein pots, and the introduction of the Dwight & Lloyd sintering machine came still later, it seems fair to say that lead smelting has been looked upon as being a rather commonplace operation, which depended for its success largely on plenty of flux and good furnacemen, and that, if not actually neglected by the metallurgist, it has at least not been studied as zealously and assiduously as have some of the newer processes. Mr. Rigg deals in a thorough and practical way with actual problems of a nature similar to those that present themselves to every smelter superintendent. For instance, he says that a foreman in charge of the Dwight & Lloyd department found that the sulphur content of the sinter he produced varied, not directly but inversely, as that of the material received from the pre-roasters. This seems paradoxical, but it was true. It appears that the pre-roasting was done on a primary Dwight & Lloyd machine, the product from which was crushed by rolls in preparation for the second treatment. The better the pre-roast, the harder was the sinter, and the greater was the proportion of coarse material in the crushed product. Less sulphur was then removed in the second roast and the sulphur content of the final sinter was accordingly high. The improvements made at the Port Pirie plant

illustrate the value of intelligent and painstaking research and experimental work and suggest in particular, as Mr. Rigg concludes, that the "last word has not yet been said in regard to the method of blast-roasting the ore and smelting the sinter in blast-furnaces".

THE effort to prosecute those responsible for the Bisbee deportations of July 1917 seems unlikely to lead to any convictions. The first test case ended in an acquittal on April 30 at Tombstone, as recorded in our issue of May 15. The next case is set for November, but we think it unlikely that it will come to trial, owing to the apparent difficulty in persuading any jury that a crime was committed, even if a blunder was perpetrated. On the other hand, it is pleasant to recall the fact that out of the Bisbee trouble there has come one good result at least, namely, the adoption of the scheme ordered by the President's mediation committee, of which the Secretary of Labor, Mr. William B. Wilson, was chairman. The managers of the mines and their employees were compelled to adjust their quarrels by means of a grievance committee, the members of which had to be elected by secret ballot and on neutral ground. Any complaint from the employees is referred to the grievance committee, which either rejects it or takes it up with the manager; in case of disagreement the matter is then referred to a Federal mediator, who, although he has not the actual powers of an arbitrator, is virtually enabled to act as such, because in every case so far his decision has been accepted by both sides. This arrangement will continue so long as a state of war persists; it holds good for all the copper mines of Arizona; and in effect it settled the labor controversy in the South-West for the term of the War. We hope that it may become established, for it works admirably. Among its minor features it is noteworthy that the men, by reason of the secret ballot, showed good judgment in the selection of their representatives, choosing both union and non-union men, much to the chagrin of the walking delegates but greatly to the satisfaction of those, managers and men alike, who earnestly desire to promote fair play in industrial affairs.

The Conventions

In a recent article Señor Blasco Ibañez remarked that the people of the Latin countries are restrained by the fear of the ludicrous. He might have included the British; their sense of humor likewise is largely perverted into a dread of making themselves ridiculous. This is intimidating; it is tyrannous; Ibañez likens it to the fear of the inquisition, and then proceeds to say, apropos of the suffragette picketing at the Chicago convention, that in a Latin country "it would be impossible to assemble a dozen ladies of respectable age and dimensions to dress themselves up like schoolgirls and parade in the streets. The thing would strike them as utterly preposterous". It would indeed, and that may be why, lacking the courage, the Spanish and Italian women have not won the vote. The conventions at Chicago and San Francisco proved our people indifferent to any fear

of seeming absurd; they made themselves intensely ridiculous by their antics and yet retained their self-respect. Macaulay's New Zealander or Butler's citizen from 'Erewhon' would have been moved to homeric laughter, not wholly good-natured perhaps, at the performances that preceded the selection of the next President of the United States. Even to the sophisticated and comprehending spectator, to the thoughtful student of our political system, the antics of the political mobs that represented the two dominant parties in the nation affords cause for regret and chagrin. The organized applause, the hired bands, and the paid yell-leaders were hardly worse than the opening invocation, which simulated a prayer to the Almighty while really only a speech to the audience, or the exploitation of the national flag and the national anthem alike in the interest of the individual candidate. Of the many speeches, most of which we read, for our sins, we recall only one that we would be willing to read again, and that was the opening address by Mr. Homer S. Cummings. The other key-note address, by Senator Henry Cabot Lodge, left an unpleasant taste of personal rancor toward a stricken man and of narrow partisanship unrelieved by any touch of generous vision. Much the worst nominating speech was that of Mr. Charles S. Wheeler in support of Senator Hiram Johnson and the best that of Mrs. Douglas Robinson in seconding General Wood. The most effective nomination was that made by Mr. Frank B. Willis, who closed a short speech by saying: "Well, boys and girls, let's nominate Harding." Mr. Willis, by the way, was the man who defeated Mr. Cox for the governorship of Ohio in 1914. Another felicitous recommendation was that made by Mrs. Jewel Brown, who said of her candidate, Mr. John W. Davis: "He is not a preacher but he practises what the preachers preach." These were rare flashes amid the fog of platitudinous piffle. As for the platforms, both are a mass of evasive verbiage. The Republican contains 6396 words; the Democratic is equally long. As Mr. Woodrow Wilson said during the 1912 campaign, "A party platform is not a program". It is an elaborate gangway for stepping into power, a political posturing that deceives some and binds nobody. Both conventions were essentially political mobs that came to heel at the call of the bosses. That was inevitable; without bossing they would still be mulling around in helpless confusion. At Chicago the crowd of politicians was moved scientifically by the old machine in the masterful hands of Senator Penrose. The reactionary element, representing a highly organized phase of predatory politics, won easily. A 'regular' was nominated, a colorless docile henchman was made the standard-bearer. Whereas the present incumbent of the presidential chair has assumed an autocratic power repellant to thousands of good citizens, his proposed Republican successor is a second-rate politician who is expected to be wholly amenable to a senatorial coterie. The pendulum will make a full swing if the Republicans succeed in electing Senator Warren G. Harding. In San Francisco the Presidential machine dictated the platform and ensured a tribute of praise to

the outgoing Chief Executive, but it declined to nominate a candidate recommended by Mr. Wilson. Here the bosses became effective by distributing the votes of the pivotal States, those of New York, Illinois, and Indiana, in such a way as to defeat the forces of the Administration and after systematic delay compel the nomination of Governor James M. Cox of Ohio. He is a man of some character and considerable achievement, but it is unlikely that he will win the race under the handicap of the outgoing Democratic regime. To earnest men the forthcoming election presents no scope for enthusiasm, and yet we agree with Mr. Hoover that those of liberal mind must do the best they can from within the existing parties. A third party would make for a confusion subversive of our political system. For the present the sanely progressive elements whom Mr. Hoover would have represented are submerged. They may make themselves felt in the cabinet of the next President, for it is quite probable that a weak man will fortify himself by selecting strong men for his cabinet, in contrast to a President of strong character who filled the offices of State with weak men. Co-operation between the Executive and Legislative branches of the Government is essential; the experience of the last twelve months is eloquent on that point. It even seems a pity that the selection of a President, who is the chief of a victorious party, is not left to the members of that party in the House of Representatives. Originally, under the Constitution, the electors were highly respected citizens chosen from each State with authority to select a President. Owing to the inability of men who were unknown to each other to concur in a choice, the arrangement broke down; so eventually the electors accepted a mandate from the electorate and became the mere recorders of the popular vote. This led to the party ticket, which is the expression of a choice made at a party convention. Today, thanks to improved transportation and communication, the system as originally devised under the Constitution would work much better than it did a century ago and it would probably lead to the choice of men of a higher type. A thousand men in open assembly never did, and never will be able to function intelligently in the choice of a representative. In a multitude of counsellors there is only noise. So long as the present system survives, the nomination of a president will fall into the hands of those small groups of quick-witted men we call political machines. Sometimes they are outwitted by Providence and we are given a Lincoln or a Roosevelt, but most of the time they give us the cigar Indians of the political sidewalk.

News From Mexico

Letters from Mexico bring cheerful news; there is an increasing confidence in the near prospect of a restoration of order and it would appear as if the provisional government of De la Huerta were being well established, in preparation for the general election of September, when General Alvaro Obregon is assured of election to the Presidency. Officials at Washington are watching the

course of events closely with a view to determining when it will be proper to recognize the provisional government, which is the *de facto* successor of the Carranza administration. Señor Iglesias Calderon, a special envoy from Mexico, is now at Washington making every effort to persuade the Acting Secretary of State that his government is worthy of recognition and support. We hope recognition will be accorded soon, for it will help to confirm the status of the existing order and facilitate the financial arrangements necessary to the rehabilitation of the railways and other industrial activities of a mining region in which our people have a large stake. Complaints reach us that the representatives of mining companies find themselves still facing many of the predatory officials appointed by Carranza; as yet apparently the new government has not been able to make a clean sweep. We would counsel patience; give President De la Huerta a chance; in the land of *la mañana* it is necessary to allow for the element of time even when the best intentions actuate the policy of a government that has just jumped into the saddle. The resumption of order and the revival of industry in Mexico must be left to the Mexicans themselves; the recovery of the country must be brought about mainly by the forces from within, not by interference from outside. The Mexican planks in the platform of our two parties are humorous. The Democrats give credit to the Wilson administration for the recent improvement south of the Rio Grande, whereas, of course, the vacillating policy of Washington during recent years has served chiefly to aggravate the troubles of our so-called sister republic. The Republicans echo the truculent tone of the Fall resolution, and expect Mexico to amend her constitution to suit our desires, but if we can persuade our neighbor in a friendly way not to give a retroactive interpretation to the clause nationalizing the subsoil we shall have done as much as we can do in that direction. For the rest, all the miner asks is life, liberty, and the pursuit of his occupation under a civilized code, whereby the Mexican government will not discriminate against him so long as he obeys the laws of the country; and in doing his legitimate work he asks for the protection of his own government whenever or wherever his just rights are invaded or suppressed by any other government. Several minor revolutionary outbreaks have been reported during the past month, but they represent, we hope, the crackling of vagrant sparks of unrest on the edge of the latest revolution. Villa is still at large and is trying to bluff the authorities into recognizing him as a political unit. He has ceased to be that, and if the new government is to receive recognition it devolves upon it to perform its proper function by extinguishing this vile ruffian, who has too long menaced life and property in the North. The rehabilitation of the railroads and the restoration of the school system are the two primary needs of Mexico. After that, and while these reforms are in progress, we may hope for a re-establishment of conditions favorable to industry. Not for ten years have the prospects been so good for the miner in Mexico.

DISCUSSION

The Camp Bird, Mr. Agnew, and Mr. Spurr

The Editor:

Sir—I had occasion some little time ago to write to the editor of the 'Engineering and Mining Journal', New York, calling his attention to the incorrectness of some remarks published in that journal on 14th February last. Since the date of that letter I have carefully sought for its publication, an acknowledgment of error on the part of the editor, or a reply direct to me, in each case without success. I conclude therefore that the editor of the journal in question intends to ignore my communication. I enclose herewith a copy of the latter and I shall be grateful if you can arrange to publish same in the 'Mining and Scientific Press', together with this explanation.

JOHN A. AGNEW.

London, June 14.

Copy of letter follows.

No. 1, London Wall Buildings,
London, E. C. 2.
10th March, 1920.

The Editor,

Engineering & Mining Journal,
New York, U. S. A.

Sir—My attention has been called to the paragraph in your issue of 14th February, relating to the Camp Bird deep tunnel.

It is a matter for surprise that you should not have taken steps to ascertain the correctness of the statement to effect that the mine had been shut down before publishing same. It is true that you mention it as being reported to you, but the deductions you draw therefrom and the peculiar satisfaction expressed, leave no doubt as to your belief in the report.

As one of the technical advisers to Camp Bird Ltd., I may be permitted to reply to your remarks. Some years ago—to be accurate, in 1908—Mr. J. E. Spurr was called on to advise the Camp Bird directors as to the policy to be followed in further development work. In the east end of the mine the then lowest working was the No. 3 adit-level. In the course of an exhaustive report, made no doubt after an examination of a similar character, Mr. Spurr advised the board that any further work below the No. 3 adit would be useless and unproductive: in spite of this advice the board decided to sink No. 3 shaft and between No. 3 adit-level and the ninth level—a vertical distance of about 1000 ft.—in a short shoot of ore in the vicinity of the shaft referred to, there has since

been extracted ore which has actually yielded a profit of over £500,000.

To sink below the ninth level would have meant enlarging No. 3 shaft and the installation of much heavier winding and pumping equipment; there was, moreover, the constant danger of the workings being flooded if any connection were established with certain water courses believed to traverse the No. 1 shaft section, the latter being an extremely wet section. These factors caused the directors, largely on the advice of the writer, to agree to the driving of the tunnel now referred to. It did not seem too much to ask that a moderate percentage of the profits won from the shoot of ore above referred to should be set aside to seek for its continuance in depth, especially when the then lowest level—ninth—appeared promising.

Whether Mr. Spurr's opinion was sought, in earlier years, in order that the directors might have the benefit of his advice on driving a low-level tunnel, I do not know: I do know, however, that it was not asked for when the question of driving the present one was under discussion.

The Camp Bird mine is not shut down; work is actively proceeding in the eastern section—the one referred to above, and a commencement is being made to extend the west drive on the vein, at the tunnel level, under No. 1 shaft section.

Am I right in assuming that the Mr. J. E. Spurr, mentioned in the paragraph I have drawn attention to, has no connection with Mr. Josiah Edward Spurr, the editor of the 'Engineering and Mining Journal', or is it permissible for one of them to seek a cheap form of notoriety while the other has a sneer for a body of men possessing what is often enough lacking today in mining—a little pluck and enterprise?

Yours faithfully,

JOHN A. AGNEW.

[We know Mr. Agnew to be a distinguished member of the mining profession and a man of the highest character. We are willing therefore to give him the space to make this protest. Why Mr. Spurr did not publish it, we are at a loss to surmise.—EDITOR.]

Professional Ethics

The Editor:

Sir—Referring to your critical editorial upon the code of ethics proposed by the American Society of Mechanical Engineers, I would call attention to that adopted by the American Society of Civil Engineers in 1914, which reads as follows:

It shall be considered unprofessional and inconsistent

with honorable and dignified bearing for any member of the American Society of Civil Engineers:

1. To act for his clients in professional matters otherwise than as a faithful agent or trustee, or to accept any remuneration other than his stated charges for services rendered his clients.

2. To attempt to injure falsely or maliciously, directly or indirectly, the professional reputation, prospects, or business, of another Engineer.

3. To attempt to supplant another Engineer, after definite steps have been taken toward his employment.

4. To compete with another Engineer for employment on the basis of professional charges, by reducing his usual charges and in this manner attempting to underbid after having been informed of the charges named by another.

5. To review the work of another Engineer for the same client, except with the knowledge or consent of such Engineer, or unless the connection of such Engineer with the work has been terminated.

6. To advertise in self-laudatory language, or in any other manner derogatory to the dignity of the Profession.

Article III, Clause 6 of the constitution of the society provides for the expulsion of a member for cause. Unprofessional and dishonorable conduct would clearly constitute such cause. This code is simple and brief. Means of enforcement, or rather of punishment for breach, are not wanting and I believe have been exercised upon one or more occasions in the past.

San Francisco, July 3. ROBERT HAWXHURST JR.

Question and Answer

The Editor:

Sir—In your issue of June 26 you invite criticism of your book on technical writing. The following is not a criticism, but a suggestion. The suggestion I would make is based on the benefits I have received from a certain work on mining, namely, Mr. J. E. Spurr's 'Geology Applied to Mining'. I have got more out of Mr. Spurr's book than all the books on mining I have ever read. I believe this is due to the manner in which the subject is presented, that of question and answer. The answers to questions are easier found and are easier fixed in the mind. I believe it would be an improvement if all subjects were presented in the same way, at least to the beginner. It may be that this method of presenting a subject is not suited to addressing those who already know a great deal about it.

Not only is it an advantage to present a subject this way, at least to a beginner, but it is, I believe, an advantage to a writer in preparing his subject, even if he doesn't present it to his readers that way. The following will illustrate what I mean. Just before the War I put in two years prospecting in Central Africa for a mining company; and, for my own satisfaction, I worked out the best way of doing every part of my work. In this I was greatly assisted by using the method of question and answer. Following is an example.

Cutting down the cost of prospecting. What items enter into the cost of prospecting? What is practically a salary and expenses from the time a prospector leaves America until he returns, his food while in Africa, the cost of administration, the wages and up-keep of the men in his employ, his outfit and tools. What does all this amount to? I can't say exactly, but for the purpose of discussion I will say about \$7000 for the term. How much time does a man spend in the field? About 19 months at the most. Then according to these figures it costs at least \$12 per day for the time a man is actually prospecting in the field? Yes. Are there circumstances under which it may cost more? Yes. What are they? Sickness and loafing. Then it pays the company for a prospector to pay considerable attention to his health? Yes. Does good management cut much figure in the cost of prospecting? Yes, a very big figure. In what ways can a man increase his effectiveness in the field? By not doing anything more than is necessary in finding what is wanted; and by devising ways and means of doing quickly what is to be done. What do you consider the most desirable thing to find? Big enough bodies of ore and gravel of a grade that it will pay to put in railroads, etc., or reduction plants. Why not put in a great deal of time looking for small bodies of high-grade ore and gravel? Because the chances are greater to make more out of the big lower-grade bodies of ore and gravel. It is a law of mineral distribution that the amount of mineral in rich veins and deposits is small as compared to the amount in lower-grade veins and deposits. This law is a very important factor in mining. Don't you think it would be profitable to pay more attention to the small high-grade ore and gravel deposits? It is not a question of what is profitable, it is a question of what is most profitable. If railroads or machinery were put in on account of big low-grade stuff, the small rich stuff would then become more profitable. What do you consider unnecessary work? Accurate surveys of streams, trails, routes, or lodes, and the surveying of small streams unless they are to be prospected to get more detailed information. The sampling of small streams, or at least an extensive sampling of them, when the streams around them have not proved good. And sampling any stream any further than to draw comparisons with the best or until we wanted to know the amount of gold in it with the idea of exploiting it. The building of trails any better or putting any more time on them than the amount of travel warrants. Or building houses any better than the length of time they are to be occupied warrants. The cutting of plantations when it is possible to get food from the outside. The planting of anything that won't mature soon enough to be used. In what other ways can a man do prospecting cheaper and quicker? By employing outsiders to do all the work than can be done by outsiders, such as cutting trails, leaves for houses, sticks, clearings, plantations, portage, etc., and using the services of various *chefs de postes* and commercial agents in arranging for food and portage. May not the employment of outsiders to do all this work cost more? It would appear

so if we only consider the wages and up-keep of one's own men without considering the cost of administration, the salary and expense of the prospector from the time he leaves America until he returns. But if we consider these items it would have to cost considerably more than it does to be profitable for one to use his own men for this work. Every day one loses in actual prospecting costs at least \$12. By employing outsiders we make a more effective use of the over-head expense—the constant expense.

The method of question and answer can be employed to great advantage in working out the problems of any business. It is surprising how readily some pretty knotty problems can be solved by putting down questions as they occur to you and then answering them. Every question when uttered seems to call forth an answer and every answer seems to suggest another question. Try it. The effect is a little surprising. By asking a question we give ourselves a definite task to perform, which helps immensely.

At all times a writer, in discussing a subject, is answering questions, only he doesn't utter them or write them down. By writing down the questions or uttering them the writer gets a clearer and better idea of his subject. He may afterward, in presenting his subject, omit the questions.

WM. CROCKER.

Prescott, Arizona, July 1.

[It so happens that we drew attention to the usefulness of Mr. Spurr's book, on the application of geology to mining, in our issue of June 26 (page 927). We agree with Mr. Crocker that the value of this handbook is enhanced by the method of question and answer. Undoubtedly the written record of questions pertinent to any subject under discussion helps to fix the essential points, but most men try to accomplish this by making mental notes.—EDITOR.]

Electric Detonators

The Editor:

Sir—The article on this subject in your issue of June 19 is most interesting. However, the recommendation about a three-pole switch will not, in my opinion, eliminate the most common causes of misfires. In the fourth paragraph of their conclusions, the authors of the paper suggest two objections to the use of delay-action exploders in cut-holes, and recommend the use of instantaneous exploders. While their suggestion is feasible, provided the three-pole switch be used as described, it is directly contrary to the recommendations of the mining division of the Industrial Accident Commission that instantaneous exploders shall not be used in the same circuit as delays. It is possible with a lighting current and a three-pole switch having one leg shorter than the other two, to use the instantaneous exploders in the same circuit as the delays. If a lighting circuit is not used there is no way to use the combination successfully. Delay-action detonators as a rule are so made that the first delays are

timed to pull the cut-holes satisfactorily, and they can be used with any kind of current, provided the wires are properly connected.

The authors also make a point of the fact that misfires may occur by using delays in the cut-holes. There is no more of a chance of electrical failure in using No. 1 delays than there is in using instantaneous detonators.

Again, referring to the three-pole switch discussed in this article, it should be borne in mind that this method is liable to cause trouble unless one of the poles is considerably shorter than the other two poles in the switch, and unless the contact is made very slowly at the time of throwing the switch. Moreover, users must be sure that they do not get a lead wire from the delays connected to the short pole. It is essential that the delays be ignited first, hence they must be connected to the long pole. All of these points are likely to be neglected by men who do not appreciate the need of care, with the result that men may be injured by accidents due to misfires.

G. CHESTER BROWN.

San Francisco, July 1.

Apex Litigation

The Editor:

Sir—I have been a frequent reader of your paper. Your appeal for aid to help solve the apex problem no doubt will attract the attention of many mining men of this country. The time is most appropriate to make an attempt to correct the many mistakes made concerning the present procedure in apex cases in court.

In response to that call you will please find enclosed a printed sketch or map showing the vein system of the Coeur d'Alene district with the Bunker Hill vein as the mother vein of the entire system. This map represents approximately thirty miles of the Bunker Hill vein, including the later veins of note that branch out from both foot and hanging wall. If there was an extension of thirty miles more added to this map it would then fail to reach either end of this great vein. There is nothing in connection with this map and the lines representing the veins of the Coeur d'Alene that has been borrowed from anyone—not even from Germany. And, furthermore, there is nothing I can borrow from geology as it is being taught in our higher institutions of learning concerning the structure and the power that have created all mineral veins and earthquakes. Strange as it may seem, the earthquake that occurred in Old Mexico a few months ago sent an electric wave through every vein in this Coeur d'Alene vein system.

I have devoted a great deal of time and energy regarding this nation-wide apex problem, which has been the cause of so many serious conflicts in the mining industry. In many apex suits the testimony introduced by geologists has been so contradictory that no judge or jury could give an intelligent decision. In some cases the judge is accused both by the public and the defendants in the case as having shown some partiality in his decision. The general impression prevails that geologists

testify for the side that pays them. Such is not the case. Geologists testify honestly, each for himself along the lines that he has been schooled and trained. It has been suggested in the last few years, why doesn't the judge employ a third set of geologists to testify for the Court, that he may arrive at a non-partisan decision. The result would be that such a procedure would give the judge one more color to choose from, with no better results.

The first serious mistake is made by the prospector who does not locate a claim properly along the trend of the vein or apex. There is no branch of mining that requires greater skill in mining than the developing of a prospect into a producing mine. There are a great many cases that I can refer to, two in particular, where the Federal Mining Company undertook to develop the Bunker Hill vein between Government gulch and Pine creek. After spending approximately \$200,000 they did not touch that great vein at any point. On the Senator Clark vein on Sunset mountain, after spending an enormous amount of money in development work, they do not know whether the vein they should have developed is six feet wide or one hundred feet. Those are conditions that confront us today, that make mining such a hazardous risk.

The time is near at hand when those who testify in mining suits, especially as to the apex of a vein, must prove it by some method. Theory has got to be such a vexed question in past years. If those that are interested in mining and the higher institutions of learning would recognize the great almighty power, electricity, that has created all things, then, and not till then, will this apex problem be solved.

There is so much that can be written on this subject, other than that taught by high institutions of learning, that when the time comes that I must defend the apex of a vein in court the problem will be solved along the lines as expressed in this paper.

JOHN J. PRESLEY.

Kellogg, Idaho, June 28.

[We publish this letter, although we are not in agreement with the writer's views in regard to the part electricity plays in the formation of veins; as to that we plead ignorance; but we do wish to endorse Mr. Presley's suggestion that the locators of claims should take more care to ascertain the strike of the vein they desire to exploit. Much of the litigation is due to random locating. —EDITOR.]

Copper in China

In 1918 over 8000 short tons of copper ingots and slabs valued at about \$5,000,000 was imported into China. An increased amount was imported in 1919. The imports for the first three-quarters of that year amounted to over 14,000 tons, but final figures for the total year's importations are not yet available. Practically all of this copper came from Japan and was minted into coins. Recently some American copper has reached China through the Japanese dealers. Copper has been used in

China since before the Christian Era; it forms a large part of the old bronze objects of those days. The metal has been produced in China for centuries, but never, so far as there are any records to show, in quantities which today would be considered of importance. Many occurrences of copper ores are known, but so far no large copper mines have been developed. These ores are scattered throughout a number of the provinces of China and the copper produced is derived from these small properties. The production of copper in China now amounts to about 2000 tons annually which does not nearly supply the demand. Copper probably has a relatively larger utilization in China than in other agricultural countries. Copper objects of art and brass utensils are quite common. The brass 'cash' pieces, 10 to the cent, and the large 1-cent and 2-cent copper pieces which are, by the way, much larger than the coppers of the United States, are in use everywhere. The 2-cent piece is about the size of the American silver half dollar and the 1-cent piece is, approximately, one-quarter of an inch less in diameter.

According to the Chinese maritime customs, imports of copper bars, rods, sheets, plates, nails, and wire amounted to 1,276,266 lb. in 1916, 1,376,400 lb. in 1917, and 1,380,933 lb. in 1918; imports of copper slabs and ingots totaled 3,474,000 lb. in 1916, 3,687,733 lb. in 1917, and 16,187,733 lb. in 1918. The final figures for 1919 are as yet unavailable, but the total tonnage for the first three quarters of the year was 28,973,200 lb., showing that a further large increase took place during that period. Japan furnished 3,206,800 lb. in 1916; 212,000 lb. came from the United States and possessions; 212,000 lb. was credited to Great Britain. The share of Japan increased to 3,647,866 lb. in 1917 and to 16,238,533 lb. in 1918. Changsha led all the rest in the volume of copper imported in 1918 and 1919. The reason is not difficult to find. Changsha is the capital of the Province of Hunan, which has been overrun by the armies of the North and the South and is now in a bad financial condition. In 1918 the Southern troops were driven out of Changsha and the city was looted. It is now occupied by the Northern forces. Since the occupation, the mint has been coining copper. Approximately 30 tons of copper and 3 tons of zinc are melted and cast into slabs each day. The melting at the Changsha mint is done in crucibles of Japanese make for most part, although a few new English crucibles recently arrived. Approximately \$800 worth of crucibles are used daily, it is said. The cast slabs are then cold-rolled on old German rolls into strips; many of which are defective, full of holes and cracks. These are then punched and stamped on small slow-working German machines which punch two blanks at a time. The dies formerly made by the Japanese are now being made at the mint by Chinese workmen. Defective coins and other scrap are re-melted in small clay crucibles made in the mint, and re-cast.

ONE-THIRD of the average man's time is spent in recreation. Every mining camp, if it desires to progress, must recognize that wholesome and health-building facilities for recreation are a necessity.

Centrifugal Pumps

By ROBERT S. LEWIS

The first centrifugal pump built in the United States was in 1818. It was called the Massachusetts pump, and was of crude design. Evidently the early pumps were not considered a success, for the wide use of centrifugal pumps has developed rapidly only during the last few years.

MECHANICS. The centrifugal pump depends for its action upon transforming the kinetic energy of a rapidly revolving mass of water into a pressure that forces the water through the pipe-line. A high velocity is imparted to the water by the action of the rotating impeller, the correct design of which practically controls the efficiency of the pump. The effect that the shape of the impeller-vanes has on the velocity of the water, as it leaves the tip of the vanes, may be understood easily by studying Fig. 1.

Let V = velocity of the water relative to the vane.

U = peripheral velocity of the vane-tip.

Then by vector addition W is the absolute velocity of the water as it leaves the impeller. The total head developed by the pump is $H = \frac{W^2}{2g} + \frac{U^2}{2g} - \frac{V^2}{2g}$, where g is the acceleration due to gravity. This total head, H , is made up of two parts: the velocity-head $\frac{W^2}{2g}$, which may be converted into pressure-head, and $\frac{U^2 - V^2}{2g}$, the pressure-head developed within the impeller. If the losses due to shock and friction be neglected, this formula holds for all pumps in which the water enters the impeller radially, and consequently applies to nearly all centrifugal pumps.

In Fig. 1 it is evident that with constant speed of rotation, U is constant, but W is the resultant of U and V . The velocity, V , of the water relative to the vane increases with the amount of water delivered. In case the impeller-tip is at right angles to the tangent at the circumference, that is, is radial, any increase in V must entail an increase in $\frac{W^2}{2g}$, but $\frac{U^2 - V^2}{2g}$ is diminished. If the vane-tip is inclined forward, the increase in W is very rapid. If we substitute for W^2 its value in terms of U and V , $V^2 + U^2 + 2UV \cos \Theta$, where Θ is the angle between the tangent and the direction of the tip of the vane, the expression for H becomes $H = \frac{U^2}{g} + \frac{UV \cos \Theta}{g}$.

As $\cos \Theta$ is positive for all values of Θ less than 90° , it is plain that for this type of impeller the greater the amount of water delivered, the greater is the head developed. When $\Theta = 90^\circ$, cosine Θ is zero. Therefore the head is constant for all deliveries and is equal to $\frac{U^2}{g}$. For backward-directed vanes Θ is greater than 90° and $\cos \Theta$ is negative; consequently the head developed de-

creases as the delivery increases. A graphic representation of these different conditions is shown in Fig. 2, 3, and 4.

A knowledge of these simple relations will go far toward ensuring a clear understanding of the apparently confusing behavior of different centrifugal pumps, and it emphasizes the fact that a centrifugal pump should be designed for the particular work it is to do. The efficiency of a well designed pump may be considerably

Fig. 1

Fig. 2

Fig. 3

Fig. 4

diminished by using the pump under conditions different from those for which it was intended.

Before a centrifugal pump can be properly adapted to its work it is first necessary to know how the capacity varies when the pump is operated at constant speed against different heads. The curve obtained by plotting the capacity or pump-discharge against the head is called the pump-characteristic. Fig. 5, 6, and 7 show the characteristics and efficiencies of the impellers illustrated in Fig. 2, 3, and 4 respectively. The efficiencies are taken from the same scale as the heads, but the figures are to be read as percentages. Brake horse-power curves are also given, but these curves are merely to show the general behavior of different pumps and not all are placed in exact position on the charts. The flatter the efficiency-curve at its highest part, the wider is the range of capacity without serious loss in efficiency. It is evident that the pump of Fig. 5 can maintain a high efficiency for a fairly large variation in discharge, but the pumps of Fig. 6 and 7 must be operated with nearly the discharge

for which they are designed in order to secure maximum efficiency. For a rising characteristic the delivery increases with increase of head and, consequently, the power required for driving the pump must increase. The more drooping the characteristic, the less will be the power required for increased delivery. Centrifugal pumps should be designed so that power-demand falls off sharply after the point of maximum efficiency is reached. Such a design makes it impossible to overload the pump-motor. A poorly designed pump might have a power-curve as shown by the dotted curve in Fig. 5. A break in the pipe-line near the pump would reduce the head nearly to zero, the discharge would be increased, and the increased power required might overload the motor so seriously as to burn it out.

In a centrifugal pump the maximum energy is possessed by the water at the instant it leaves the impeller-vane. Part of this energy is in the form of pressure-head and is $\frac{U^2 - V^2}{2g}$. The remainder is kinetic energy or velocity-head and is $\frac{V^2}{2g}$. The ratio between these two quantities depends upon the shape of the impeller-vane and also upon the relation between the velocity, V , of the water relative to the impeller, and upon the peripheral speed, U , of the impeller. In general, the velocity of the water in a radial direction as it leaves the impeller is from 10 to 15% of the peripheral velocity.

The efficiency of the pump as a whole depends upon the efficiency with which the impeller-pressure $\frac{U^2 - V^2}{2g}$ is generated and the efficiency with which the velocity-head $\frac{V^2}{2g}$, possessed by the water as it leaves the impeller, is converted into pressure. Efficiency within the impeller is secured by correct surfaces, curves of large radius, and smooth finish. It is desirable to develop as much head as possible within the impeller, because the greater the velocity-head of the water as it leaves the impeller, the more unsuitable is the form of the head-characteristic curve.

With an impeller of constant diameter the following relations hold:

The discharge of the pump varies as the speed of the impeller.

The head developed varies as the square of the speed.

The power required varies as the cube of the speed.

If the speed is the same, impellers of different diameters have these relations:

The discharge varies as the diameter of the impeller.

The head developed varies as the square of the diameter of the impeller.

The power required varies as the cube of the diameter of the impeller.

The equation for the total head against which the pump must deliver is

$$H = h_s + h_f + h_v$$

where h_s = the static head or lift in feet

h_f = the friction-head in feet

and h_v = the velocity-head in feet, or the head required to give the water the velocity it has

in the pipe, and is $\frac{v^2}{2g}$ where v = velocity in feet per second

For long pipes the friction-head is usually the largest part of the total head. The friction-loss in pipes varies approximately as the square of the velocity, so the importance of keeping the velocity down to a reasonable figure is evident. The question of the make-up of the total head against which a centrifugal pump must work has an important bearing on the performance of the

pump, that is, whether the head is all static, part static and part friction, or practically all friction-head.

The volume delivered by a centrifugal pump increases directly as the speed, but the head developed increases as the square of the speed. If the head pumped against is entirely a friction-head, its value varies as the square of the velocity of the water in the pipe. The velocity varies with the delivery, hence the head must vary with the square of the delivery. Under these conditions practically constant efficiency is secured for all deliveries and at all speeds.

Should the head be partly static and partly frictional the efficiency would vary with the delivery and the pump should be designed to give maximum efficiency at one definite head and delivery. If the curve is flat, the effi-

iciency will not change greatly with moderate variations in head and delivery.

These points may be made clear by explaining the method of testing a pump to determine all its characteristics and to learn whether it fulfills the guarantee of its maker. The details of testing will be considered later, but the general factors involved will now be considered.

The pump is operated at constant speed. First, it is primed and started with the discharge-valve wide open, and the following data are noted or calculated:

Discharge in gallons per minute

Total head developed in feet

Efficiency of the pump

Brake horse-power

Revolutions per minute

The discharge-valve is closed slightly and a second set of readings is taken. Then the valve is closed farther and readings are again taken. This method is continued until the last set of readings is taken with the valve tightly closed. This point is called the 'shut-off', and is important in the selection of a motor for driving the pump. Table I shows the data derived from a test on an eight-inch pump.

Gallons per minute	Head, feet	Efficiency, %	Brake horse-power	Revolutions per minute
0	111.0	0.0	28.0	1420
400	114.0	30.0	38.0	1420
800	114.0	52.0	44.5	1420
1200	110.5	65.5	51.0	1420
1600	102.0	72.5	56.5	1420
1800	95.0	73.2	58.5	1420
2000	86.0	72.5	60.0	1420
2200	76.5	70.0	61.0	1420

These results are plotted in Fig. 8. The highest point on the head-curve is 114 ft. Therefore, the pump will not deliver against a greater head. The maximum that the pump will deliver is about 2400 g.p.m., but, as will be observed on the chart, the head at this capacity would be zero. With the discharge-valve closed, the usual condition when starting a centrifugal pump, the shut-off horse-power is 28 and the head developed is 111 ft. The highest efficiency, 73.2%, is reached at a head of 95 ft. At this point the discharge is 1800 g.p.m. and 58.5 hp. is required. This is the service for which the pump is designed. However, the efficiency-curve is rather flat near this point, so that changing the head (with a corresponding change in delivery) through a moderate range would reduce the efficiency but little.

The static head against which the pump works is 80 ft. as marked by the horizontal line on the chart. The friction-head, which varies approximately as the square of the velocity of flow, or as the square of delivery in gallons per minute, is shown by the curved dotted line. The friction-head curve is so placed that any point on it gives the total head on the head-scale. Of course these two lines are independent of any characteristic of the pump. For this reason the point of intersection of the head-characteristic and friction-head curves gives the limit of capacity of the pump, approximately 1950 g.p.m., unless the head is reduced to zero, in which case the discharge will be 2400 gallons per minute.

If the pump is to be used for a lower head than that

for which it was designed, care should be taken that the motor is not subjected to an excessive overload. At the point of maximum efficiency the required horse-power is 58.5. The maximum load that could be thrown on the motor is 61 hp. at zero-head. There is no danger of a serious overload here. But suppose that the pump was to discharge 600 g.p.m. The head would then be about 114 ft. and the brake horse-power about 40. The efficiency would be too low for real working conditions, but this serves as an illustration. Let a 40-hp. motor be used to drive the pump. Should the pipe break close to the pump and the head be reduced to zero, the discharge would increase to 2400 g.p.m. and the power required would be 61 hp. This would mean a 53% overload on

Fig. 8

the motor, which, if continued, would probably burn it out. The importance of using a pump under the conditions for which it was designed is apparent.

The effect of reducing the capacity of a centrifugal pump by throttling will now be discussed. In Fig. 8 the conditions of maximum efficiency are: discharge, 1800 g.p.m.; head, 95 ft.; brake horse-power, 58.5; and efficiency, 73.2%. If the capacity is reduced by throttling to 1200 g.p.m. what will be the result, considering the head as all static? From the data of the test the pump, when throttled to 1200 g.p.m., will develop a head of 110.5 ft., will use 51 hp., and will have an efficiency of 65.5%. However, this is not the useful efficiency as will now be shown. The useful or actual head remains constant at 95 ft., consequently throttling has developed an artificial head of $110.5 - 95 = 15.5$ ft., as a result of the friction of the water passing the throttling-valve. The power to lift the water is $\frac{1200 \times 95}{3960} = 28.8$ hp., but the pump requires 51 hp. Therefore the useful efficiency is $28.8 \div 51 = 56.5\%$ instead of 65.5%. Throttling produces an artificial head and its effect on the useful efficiency of the pump should be understood to avoid mistakes in operation. It is true that throttling also reduces the power required, in this example from 58.5 to 51, but the useful efficiency is not 65.5% as it would be if the pump were discharging 1200 g.p.m. against a total static head of 110.5 ft. with no throttling.

Suppose the original head of 95 ft. to be made up as follows: static head 50 ft. and friction-head 45 ft. The new capacity is to be 1200 g.p.m. as before. The friction-head varies approximately as the square of the veloc-

ity, and so may be taken as varying with the square of the capacity since the velocity is directly proportional to the capacity. The new friction-head developed by throttling is, therefore, $\frac{1200^2}{1800^2} \times 45 = 20$ ft., and the new total head is $50 + 20 = 70$ ft. The wasted head is $110.5 - 70 = 40.5$ ft. The water horse-power is $\frac{1200 \times 70}{3960} = 21.2$, but 51 hp. is required to operate the pump. The useful efficiency is $21.2 \div 51 = 41.6\%$. This makes it plain that more efficient results are obtained when the head is nearly all static than when it is largely friction-head. Throttling may be used where the capacity is to be reduced, but the speed of the driving motor cannot be changed. A permanent reduction in capacity is more efficiently obtained by reducing the speed of the pump, provided the new speed is suited to the prime mover.

Let it be required to reduce the capacity of the pump, under the original conditions, from 1800 g.p.m., to 1200 g.p.m. by changing the speed. The problem is one of constructing a new set of curves from the old ones with the aid of the relations between speed, power, head, and capacity. In Fig. 8 determine the point C' corresponding to 1200-g.p.m. discharge and 95-ft. head. This is a point on the new head-curve. Draw the curve through this point parallel to the old head-curve. To determine the new speed the cut-and-try method must be used until a point is found that falls on the new curve. Assume 1338 r.p.m. as the speed. The corresponding new capacity and head are found as follows: New capacity is proportional to the speed, so $1800 \frac{1338}{1420} = 1695$ g.p.m., the new capacity. New head is proportional to the square of the speed, so $95 \frac{1338^2}{1420^2} = 84.3$ ft., the new head. This point, A' , falls approximately on the new head-curve, consequently 1338 r.p.m. should give the desired discharge, 1200 g.p.m. A number of such calculations are usually necessary before a point is found that will fall on the curve.

A new efficiency-curve may be drawn to be used in connection with the new head-curve. Thus, points on the original head-curve are selected and transformed into points on the new one by using the two speeds as in the problem just solved. The efficiencies corresponding to the points on the original curve are transposed to a new efficiency-curve by placing these respective values under the corresponding points on the new head-curve and then connecting them. In Fig. 8, A on the old head-curve becomes A' on the new. B is the efficiency under A , so this value is placed under A' and is a point on the new efficiency-curve. As an alternative method, the point C' , through which the new head-curve was started, can be transformed into a point on the original head-curve. As C' corresponds to 1200-g.p.m. discharge and 95-ft. head, the new capacity would be $1200 \frac{1420}{1338} = 1273$ g.p.m., and the new head would be $95 \frac{1420^2}{1338^2} = 107.0 +$ ft. This gives the point C' , which should fall on the original head-curve. The efficiency, D , for this point is

also the efficiency under C' on the new curve. The value is approximately 68%.

The brake horse-power for the point C' is $\frac{1200 \times 95}{3960 \times 0.68} = 42.4$ hp. By making similar calculations for other points a new horse-power curve can be constructed. Since the brake horse-power for the throttled discharge of 1200 g.p.m. was 51, and the corresponding efficiency was 56.5%, there is a gain, both in power used and in efficiency, by reducing the speed instead of throttling the discharge, provided this lower speed can be efficiently supplied by the prime mover operating the pump.

TESTING CENTRIFUGAL PUMPS. All large manufacturers of centrifugal pumps have their own testing laboratories, and each pump must be tested to determine its characteristics and to learn whether it answers specifications. Centrifugal pumps should be purchased under a guarantee, the substance of which is often as follows: "The efficiency of the pump under specified conditions of head, capacity, and speed shall be clearly and definitely guaranteed. The pump-builder shall conduct a test to determine head-capacity, efficiency, and brake horse-power characteristic curves, and a certified copy of this test is to be furnished to purchaser".

The three points to be noted during a test are, total head against which pump works, discharge in gallons per minute, and power-input. The power-input is determined by using a driving-motor which has been carefully calibrated, and whose efficiency is accurately known under all conditions of operation. The total head is determined by gauges placed in both suction and discharge-pipes. The discharge is measured by a weir, a calibrated nozzle, a Pitot tube, or by a Venturi meter.

MEASUREMENT OF HEAD. A vacuum-gauge, or mercury manometer, is placed in the suction-pipe about two inches from the pump-flange. A pressure-gauge, or mercury manometer, is placed at a similar point in the discharge-pipe. The mercury manometer is sometimes used up to pressures of 70 lb. per square inch, though a pressure-gauge is more common. The suction-gauge is usually a mercury manometer. Pressure in pounds on the gauge is reduced to head in feet by multiplying by 2.31. Inches of mercury is converted into head in feet by multiplying by 1.132. When used thus, the pressure-gauge shows the static, friction, and velocity-heads in the discharge-pipe and the suction-gauge gives the static lift, friction-head, and head-loss due to entrance velocity in the suction-pipe. The suction and pressure-heads should be reduced to the axis of the pump-shaft as a basis for computation. In Fig. 9, D is the distance between the gauges, and should be added to the sum of the heads just found. Thus, if the pressure-gauge indicates 40 lb. per sq. in., the suction-gauge reads 20 in., and D is two feet, the total head will be $40 \times 2.31 + 20 \times 1.132 + 2 = 117.04$ ft. In case the suction and discharge-pipes are not of the same diameter, a correction must be made for the difference in velocity in the two pipes. If the discharge-pipe is smaller, the velocity in it is greater than in the suction-pipe and the pump should be credited with

the difference. If the discharge-pipe is larger than the suction, the pump should be debited with the difference calculated in terms of velocity-head. Thus if the velocity-head in the discharge-pipe is 2.5 ft. and in the suction-pipe 1.5 ft. per second, the difference should be added to the head as determined above; consequently the total head would be $117.04 + 1 = 118.04$ ft. The velocity-head is $V^2 \div 2g$, where V is the velocity in feet per second. In a centrifugal pump the water must have high velocity through the casing to obtain high efficiency so that the size of the opening of a properly designed pump is not always the best size for the discharge-pipe. The friction-head developed by the flow of water through the pipe, bends, and valves is the governing factor in selecting the proper size of pipe. To prevent excessive friction-loss the velocity in the pipe is often limited to from 6 to 8 ft. per second.

MEASUREMENT OF DISCHARGE. The rectangular weir is used for large flows of water, but the V-notch weir is

Fig. 9

Fig. 10

Fig. 11

Fig. 12

more suitable for small quantities. For a rectangular weir with end-contractions, the formula of Hamilton Smith Jr. is as satisfactory as any.

$$Q = C \frac{2}{3} \sqrt{2g} L H^{3/2}$$

where Q = cubic feet per second

L = length of weir in feet

H = head in feet

C = constant (see table below)

Table Showing Values of C

H in feet	Length of weir in feet						
	0.66	1	2	3	5	7	10
0.1	0.632	0.639	0.646	0.652	0.653	0.654	0.655
0.2	0.611	0.618	0.626	0.630	0.631	0.632	0.633
0.3	0.601	0.608	0.616	0.619	0.621	0.623	0.624
0.4	0.595	0.601	0.609	0.613	0.615	0.617	0.618
0.5	0.590	0.596	0.605	0.608	0.611	0.613	0.615
0.6	0.587	0.593	0.601	0.605	0.608	0.611	0.613
0.7	0.585	0.590	0.598	0.603	0.606	0.609	0.612
0.8	0.595	0.600	0.604	0.607	0.611
0.9	0.592	0.598	0.603	0.606	0.609
1.0	0.590	0.595	0.601	0.604	0.608
1.2	0.585	0.591	0.597	0.601	0.605
1.4	0.580	0.587	0.594	0.598	0.602
1.6	0.582	0.591	0.595	0.600

For a V-notch weir, angle 90° , the formula is

$$Q = 2.544 H^{5/2}$$

where Q = cubic feet per second

H = head in feet

Where the rectangular weir is used the edge should be of thin iron plate, sharply beveled. The depth of the water, a in Fig. 11, should not be less than one-third the length of the weir. The height of the water on the crest, H , should be carefully measured by a hook gauge at a point several feet up-stream, where the water is quiet and its surface level. Free access of air should be allowed under the stream as it falls from the weir.

In the displacement method, the water is pumped into a tank or reservoir where the volume can be accurately measured. This is an accurate method if the rise of the water during the test is sufficient to obviate small errors in measurement.

The nozzle and Pitot-tube method of measurement is reliable if a correctly shaped nozzle is used. The nozzle should be placed at the end of a straight section of pipe to obtain a smooth jet. The velocity-head may be measured by a column of water or of mercury. If the head, I , indicated by the tube is in feet of water, the velocity of the water leaving the nozzle in feet per second is obtained from the equation $V = \sqrt{2gI}$. If the diameter of the nozzle is d inches the theoretical flow through the nozzle in gallons per minute is $19.63 d^2 \sqrt{I}$. The actual flow through a well designed nozzle is from 98 to 99% of the theoretical flow. Fig. 10 shows the arrangement of nozzle and Pitot tube. The head produced must be measured from the level of the outlet of the nozzle.

Centrifugal pumps may be divided into two classes, low-lift and high-lift pumps. Low-lift pumps are generally of the volute type, and are designed to work against heads up to 150 ft. The pump-casing is in the form of a spiral or volute curve and serves to guide the water from the impeller into the discharge-pipe in such manner that the velocity-head is gradually converted into pressure-head. High-lift pumps are commonly known as turbine pumps. The impeller is surrounded by a circular diffuser with vanes so arranged as to offer gradually enlarging passages to the water. In this way the velocity of the water as it leaves the impeller is converted into pressure. These pumps are used for high heads. Single impellers can be made to work against a head of 350 ft., or even greater, but it is not usual to find pumps with single impellers working against more than 150 ft. High heads are obtained in multistage pumps or those which have more than one impeller. Each impeller draws its suction from the preceding one, and adds its increment of pressure so that the final pressure is attained only in the last stage. Pumps of the multistage type are made for heads as high as 250 ft. per stage, but modern mine practice indicates a tendency to keep the head per stage between 100 and 150 feet.

Theoretically there is no limit to the number of stages that may operate in one casing, but there is a practical limit that is imposed by the size of pump-shaft required. This depends upon the distance between bearings and the size of the casing. The number of stages in one casing is usually not more than four; sometimes six are used. For high heads the pump is really a combination

of two separate multistage units working in series. Thus, an eight-stage pump is made up of two four-stage pumps.

Separate centrifugal pumps, having the same capacity, may be connected in series to pump water against a head equivalent to the sum of the heads for which the pumps were designed. However, there is danger of splitting the casing of the second pump unless it is strong enough to withstand the additional pressure to which it is subjected.

MOTORS FOR CENTRIFUGAL PUMPS. The present practice of manufacturers is to rate motors nearly at their maximum capacity. This means that motors cannot be operated at an appreciable overload without danger of overheating. Where centrifugal pumps are to be motor-driven it is imperative that the approximate power required by the pump be known beforehand and that the possibility of any marked change in operating conditions should be foreseen so that the motor selected will not be subjected to dangerous overloading. Conservative average efficiencies of centrifugal pumps are given in the accompanying table. These figures can be used for estimating the power requirements of pumps of good design.

Size of pump, inches	Normal rating, gallons per minute	Efficiency, single stage; head up to 150 ft., %	Efficiency, multi-stage pumps; head above 150 ft., %
2	100-150	50	45
3	200-350	55	50
4	400-600	60	56
5	650-900	65	62
6	950-1300	70	68
8	1500-1800	72	70
10	2000-3000	75	72
12	3500-4500	76	73
14	5000-6000	77	74
16		78	75

The horse-power required is found by dividing the water horse-power by the efficiency of the pump. However, the motor selected should be one having from 10 to 12% higher rating than that calculated in order to take care of wear in the pump, which reduces the efficiency, and to meet the contingency of any small unlooked-for increase in the power needed.

In general, centrifugal pumps are easily started. The starting-power required is less than full operating-power, and this has an important bearing on the type of motor that can be used since the motor need not have a high starting-torque. Centrifugal pumps are nearly always started with the discharge-valve closed. Starting conditions are, therefore, the 'shut-off' conditions as described above. The power required at 'shut-off' is found from the pump curves. In Fig. 5, 6, and 7 the starting-power is given in percentages of power required under normal operating conditions. The percentages are 47, 36, and 24 respectively. Should a motor be of such design that its starting-torque was just sufficient to start the pump of Fig. 7, 'shut-off' power being 24% of full operating-power, the motor would be unable to start the pump of Fig. 6 which requires 36% of full power for starting. In some pumps the 'shut-off' may be as much as 70% of the full operating horse-power. If a pump is started with the discharge-valve open the motor has to come up to full power at the same time that it comes up to full speed, which means that the motor must be thrown onto the line at full rating instead of at only a fraction. Some squirrel-cage motors, used under such a condition, have

had their coils loosened by the heavy surges of current caused in this way. The motors that are suitable for driving centrifugal pumps are the squirrel-cage induction motor, the slip-ring induction motor, the synchronous motor and, in some cases, the direct-current motor.

The squirrel-cage motor is most commonly used for driving centrifugal pumps. Because of its simplicity, this type is used for nearly all small and medium-sized pumps. It is inherently a motor of low starting-torque and relatively large starting-current. The average squirrel-cage motor, if thrown directly on the line, takes from four to eight times normal current. Only in the case of small machines, 5 hp. and under, can the motor be thrown directly onto the line, as the rush of current resulting would cause too great fluctuations in voltage, excessive demand of current of low power-factor on the generating-station, and dangerous shocks to both pump and motor. There is a definite limit to the starting-torque that this motor can develop. The starting-torque varies from 100 to 150% of full-load torque for full voltage, and inversely as the square of the normal applied voltage. For motors of large size some form of starting-compensator is always used to reduce the starting-voltage. If this voltage is greatly reduced the starting-torque may be low. A reduction of only one-half in current would make the starting-torque one-quarter that of full-load torque. Motors of 150 hp., or even less, are generally of the slip-ring induction type. Such motors have the ability to start smoothly against a large load and draw relatively small current from the line, thus minimizing fluctuations and the danger of shocks to motor and pump.

Synchronous motors, especially of the self-starting type, are quite suitable for centrifugal-pump drives in cases where large-sized pumps are to be operated continuously over long periods. The self-starting synchronous motor has auxiliary windings imbedded in its field-poles. Bars are placed in the pole-faces and are connected by rings, so that for starting conditions resemble those of the squirrel-cage motor. When it has attained full running speed as an induction motor it must be pulled into step or synchronous speed, after which it operates as a synchronous motor. A motor of this type can have a higher starting-torque than a squirrel-cage induction motor because a high starting-torque for a squirrel-cage motor means comparatively poor efficiency at full speed. The synchronous motor drops the induction-motor characteristics as soon as it is at synchronous speed. Once up to this speed, the motor will run at constant speed independent of the voltage of the supply as long as it is within the limits of the pull-out torque. Most synchronous motors will carry an overload of 200 to 300%, and, consequently, will continue to operate a centrifugal pump at full speed although the supply-voltage should drop to a point where there would be considerable drop in speed if an induction-motor were being used. A great advantage of the synchronous motor is that it can be adjusted to give a power-factor that will have a correcting effect on a bad power-factor in the supply-line. For this reason it is well adapted to heavy

duty where fluctuations of load would ordinarily produce a low power-factor in an induction motor. However, the synchronous motor is more costly than the induction type and is not to be recommended except in large sizes, say of 150 hp. or more.

The induction and synchronous motors are essentially constant-speed motors, and the speeds are limited by the cycles used and the number of poles on the machines. If only direct current is available, or if speed-adjustment is necessary, as in the case of a centrifugal pump that must operate against different heads, the direct-current motor is useful. The motors are either of the shunt or compound-wound type, depending upon the condition of voltage in the supply-line. There is less variation in speed due to irregular voltage in a compound motor than in a shunt-wound motor. A direct-current motor will run at a lower speed when cold than when hot, because of the lesser resistance in the field-windings when they are cold. From two to six hours is usually required for the shunt-fields to attain normal operating temperature, depending upon the size and characteristics of the motor. During the time of heating the motor will operate below normal speed and the capacity of the pump will be reduced. In one case a pump did not deliver any water until the motor was up to full speed. The special field for direct-current motors for driving centrifugal pumps is city water-works, where water at constant head must be pumped in varying amounts. High pressure can be obtained for fire purposes. Direct-current motors have a high starting-torque and a more efficient method of speed-variation than either induction or synchronous motors.*

'Baking' Gold Ore

An interesting and successful method of treating the ore from the Connemara mine in Rhodesia is outlined in a communication to the Chemical, Metallurgical and Mining Society of South Africa by B. L. Gardiner. Mr. Gardiner sets forth the essential principles involved in a process which, for the sake of a better name, has been termed the 'baking process', and which consists merely in subjecting the ore to the action of heat preparatory to treatment by cyanide. It differs from the ordinary roasting process, in that the degree of temperature to which the ore is raised is much lower than that necessary for the roasting, and, further, that the presence of air or oxygen is in no way essential to its success, the appli-

cation of a certain amount of heat being all that is necessary. The net result of the introduction of the baking system at the Connemara mine has been to increase the extraction from 68 to 86%, with little or no increase in the working costs. The ore belongs to the class known in Rhodesia as banded ironstone, and at present only the upper oxidized portions of the lodes are being worked, and it is only to this oxidized ore that the scheme applies. Besides the silica and iron oxides which make up the bulk of the ore, qualitative analysis shows the presence of combined water, magnesia, and sulphates. The original plant consisted of twenty 1250-lb. gravity stamps and one 5-ft. Chilean mill as crushing units, followed by sand-leaching and slime-decantation plants, the gold being recovered by amalgamation on copper plates and by precipitation on zinc shavings from the cyanide solutions. The best results were obtained by using 200-mesh screens on the mill. The average results over a period of 12 months were: 4000 to 4600 tons per month treated, 67.9% extraction. Re-treatment of the residues failed to recover further gold, and laboratory tests merely tended to show that the plant was doing all that could be expected of it. Without the addition of lime there is an excessive consumption of cyanide, and this has been attributed to the action of ferric sulphate or basic iron sulphates. The consumption of lime is high, being from 6 to 8 lb. per ton of CaO.

The tubular drier was then designed and constructed. So far only the fine, eliminated after the rock-breaker, has been subjected to baking, the balance of the ore going through the ordinary process of milling ore, amalgamating and cyaniding. The separation of the fine and coarse is done on a shaking screen provided with 1½-in. apertures. It is estimated that the fine ore passes through the drier in 30 minutes. The time of treatment in the cyanide vats averages ten days, and the total weight of solution is at least 1½ times that of the ore treated. The consumption of lime on the baked ore amounts to 10 to 12 lb. per ton in terms of CaO. The fine ore in mass has the appearance of rather coarse gravel, some of the lumps being as large as walnuts, then grading downward. A liberal estimate of the average cost is about 1s.10d. per ton for the actual roasting, and including transport to and from the drier to about 2s.2d. per ton. The ore contains considerable proportions of hydrated oxides of iron, and when it is heated appreciable quantities of water are given off. This water, it must be understood, is not present as moisture, since it will not be driven off in a water bath at 100°C., but requires a somewhat higher temperature, and it is evident that it exists in the ore as water of combination. Mr. Gardiner concludes by saying: "As a process likely to be applicable to the generality of gold ores, baking is not likely to hold a very important place, as its success depends upon an unusual peculiarity. At the same time there may be other ores of a similar nature, and with such as these the baking process may find a beneficial application."

Lead-Smelting Practice at Port Pirie, South Australia

By GILBERT RIGG

*In the present paper I wish to offer some account of the advances in metallurgical practice which have been made at the plant of the Broken Hill Associated Smelters Proprietary, Ltd., at Port Pirie, South Australia, during the past four years. I do not propose to enter into a detailed description of the plant itself for two reasons. In the first place there is still a good deal of reconstruction in progress and to be accomplished, so that any detailed description would be out of date in a year or two, and in the second place, in general it follows the usual lines of plants carrying out the roast-sintering and blast-furnace treatment of galena concentrate, with subsequent refining of the bullion. Specific references to equipment will therefore only be made in so far as they are necessary to make clear the operating methods.

Early in 1916, it had become evident that considerable improvement both in plant and in practice had become highly desirable, and that serious experimental work on a large scale was necessary in order to provide data on which such improvements could be most economically carried out. The roasting operation was neither as thorough nor as efficient as could be wished, and this of course reflected seriously on the blast-furnace operations, which were giving a good deal of trouble. The increasing proportion of the very finely divided flotation concentrate (or slime concentrate as it is commonly called) was in part responsible for this, as at that time its treatment was not properly understood; but the roasting practice, as a whole, needed a thorough revision, as until that was set in order good results could hardly be expected. It was on this department, therefore, that our attention was first concentrated.

The lead-sulphide concentrates of Broken Hill are divided into two classes, namely, granular concentrate (from jigs and tables) and slime concentrate (from the flotation-plants). The general average composition of these two classes is as follows:

	Granular concentrate	Slime concentrate
	%	%
Lead	63.0	57.0
Zinc	7.0	11.0
Iron		
Manganese }	4.7	4.3
Sulphur	14.5	18.0
Lime	1.5	1.5
Alumina	1.5	1.0
Silica	5.0	3.5

A large proportion of the slime concentrate will pass through a 200-mesh screen.

These concentrates were formerly roasted in two different ways.

According to the first method, a mixture of the two grades, with a proportion of oxidized lead ore, mainly silicate, and also limestone and ironstone, was partly roasted in Ropp reverberatory roasters, after which the partly roasted ore was transferred to Huntington-Heberlein pots and the sulphur brought down as low as possible there.

According to the second method, the mixture was passed over a Dwight-Lloyd machine, operating as a pre-roaster, and the partly roasted sinter was crushed and passed over a second Dwight-Lloyd machine, where the elimination of the sulphur was carried as far as possible, this latter machine being the counterpart of the Huntington-Heberlein pot in the first method.

The first process gave the best results, the product from the second being uniformly poor; 5% sulphur in the final sinter was quite common, and the sinter lacked strength. Its behavior in the blast-furnaces was unsatisfactory. The Ropp roasters on the other hand took up a great deal of room and the combination of these reverberatories and Huntington-Heberlein pots did not seem to offer the same scope for economy as the double treatment with the Dwight-Lloyd machines.

Finally, while the product worked better in the blast-furnaces than the Dwight-Lloyd product it was not as good as we wanted. The final results of the investigation into the double Dwight-Lloyd method showed that at the outset we have been laboring under three serious misconceptions. These were:

(1) That the sulphur that is combined with the zinc is more difficult to roast-off than that combined with the lead.

(2) That the presence of coarse pieces of flux or pre-roast sinter are necessary in the charge in order to 'open up the bed'.

(3) That the slime is intrinsically more difficult to roast than the granular concentrate.

The first of these hypotheses received a rude shock when our attempts to blast-roast pre-roasted zinc concentrate carrying 48% zinc, came to successful fruition in 1917. Some data concerning recent developments of this method are given subsequently in this paper. At that time, however, our results showed that zinc concentrate of the above zinc content, that had been pre-roasted to 9% sulphur, could be rapidly roasted on a Dwight-Lloyd machine to 1% sulphur. Under these circumstances the reluctance of a charge carrying only 3% sulphur combined with zinc to roast to below 5% sulphur clearly needed some other explanation, and the zinc excuse was dropped, although I think I am safe in saying that the majority of lead metallurgists at that time would have concurred in it. As a matter of fact, if zinc does cause trouble it is due to the rapid evolution of heat which its roasting occa-

*A paper discussed at a meeting of the Institution of Mining and Metallurgy on May 20, 1920.

sions, this causing a tendency to fuse the galena. I do not believe, however, that this is sufficient to cause appreciable trouble.

Our second fallacy, namely, that the presence of coarse ($\frac{1}{2}$ to $\frac{3}{4}$ -in.) pieces of ironstone or limestone or sintered charge are necessary to render the charge on the machine nervous to the blast, met a similar fate. This also may be reckoned as a common belief, or was at that time, but as a matter of fact it is not true. The shrinkage of the finer part of the charge around these coarse pieces certainly does open fissures in the neighborhood, and allows the blast to pass, but these openings are localized and render the distribution of the blast through the charge uneven.

that the air passes readily between them, and by diffusion reaches the inside of the aggregate and roasts it through.

It is quite evident that pieces of free lime in the sinter have done no work during the roasting, and in consequence are wasted, besides taking up room on the machine to no purpose. Further, the crushing of the stone was an expense, and we lacked crushing capacity, and at the same time we had at our disposal a range of sand-hills composed of limestone sand (through 40 mesh), which was cheaper to obtain than quarrying solid limestone and, of course, needed no crushing. Our experiments were therefore directed to the substitution of limestone sand for crushed limestone in the roaster-charge, and the re-

THE SMELTER AT PORT PIRIE

In the case of the limestone, the coarser pieces are to be found embedded in the sinter, altered only on the surface, the bulk of the piece being simply burnt to lime. These pieces slake on exposure to the air, and cause crumbling of the sinter in consequence, which is really undoing the work done during sintering to a considerable extent.

As a matter of fact the notion that the air-blast finds its way downward between the particles of a finely divided (through 40 mesh) charge is wrong. It is quite impossible to roast such a charge dry, because the spaces between adjacent grains of ore are so small that too much resistance is offered to the air passing through. The volume of air drawn through is in consequence too small to carry on the roasting operation. By damping the charge the particles cohere into larger or smaller aggregates, and by proper mixing and handling these aggregates can be obtained of such a shape and size of grain,

sults corresponded with what would be expected if the foregoing conclusions were true. The charges worked more evenly, and the final sinter stood up much better when exposed to the weather.

The reduction in size of the ironstone to correspond with the limestone sand was not possible. In the first place we had not the crushing equipment necessary to reduce all the ironstone to pass 40 mesh, and in the second place we were dealing with a hard ironstone, the crushing of which would probably have been more costly than the advantage to be derived warranted. With no limestone to be crushed, however, we were able to crush all the ironstone through four mesh, which gave us distinctly better results, and later a further improvement, which enabled us to eliminate ironstone altogether from the charge, finally disposed of this problem. In the meantime the following experiment indicated clearly that our coarse ironstone was only a passenger.

Crushed through 4 mesh, the ironstone yielded a product of which 70% would pass through 8 mesh. A charge made up in the ordinary way was screened on an 8-mesh screen before going to the Dwight-Lloyd machine, thus eliminating all ironstone coarser than 8 mesh, and proportionately reducing the percentage of ironstone in the charge, as all the other constituents were fine enough to pass readily through the 8-mesh screen.

This screened charge roasted just as well as the charge containing the whole of the ironstone. On the other hand it was impossible to get good results when the percentage of limestone in the charge screened through 4 mesh was brought down to the same point. The coarse ironstone was obviously therefore not paying for itself.

Just how much of the work done by these added agents is physical and how much is chemical it is hard to say. They act as cooling agents, preventing premature fusion which would lock up sulphides in the fused charge, because they dilute the sulphides which furnish the fuel, and similarly absorb some of the heat produced. They also appear to have some catalytic action which facilitates the oxidation of the sulphides. We are preparing to make a close study of the actual sequence of operations in the laboratory and try to ascertain as nearly as possible the exact part which each of the constituents plays.

Much the same line of argument holds good as regards the size of the material which has passed through the intermediate crushing between the first and second roasting on the Dwight-Lloyd machines. The foreman in charge of the machines used to hold that the better the ore was roasted (that is, the lower the sulphur content was reduced) on the pre-roasting machines, the higher the sulphur content of the final sinter. This sounded absurd, but it had nevertheless a substantial substratum of truth. The better the pre-roast the harder and more sintered the material, and hence the greater the proportion of coarse material after passing through the rolls, that is, material up to $\frac{3}{4}$ -in. size. This coarse stuff upset the roasting on the final machines, and gave rise to the belief referred to above. By keeping the size of the pre-roasted material smaller than $\frac{1}{4}$ in. this difficulty may be avoided.

As regards the prejudice against slime concentrate, this depended partly on the poor results which had been obtained in the past, and partly on *a priori* considerations based on its exceedingly fine state of division. As a matter of fact, as this slime concentrate is always obtained wet, and is subsequently dried, it is usually in the form of lumps and cakes, which, if they can be brought down to a size which will enable them to roast, without disintegrating too much, so as to bring them back to fine powder, behave perfectly well on the machines.

As mentioned before, it is necessary to damp the charge, and this naturally weakens the pieces of caked slime, and helps them to disintegrate into their original fine state. If now the charge is vigorously stirred the disintegrated material works between the granules of the charge and fills up the spaces. On the other hand, if the lumps of slime are too coarse, the air cannot reach the inside.

Originally the charges were mixed and conveyed to the

machines by interrupted-flight screw-conveyors, which were driven fast, and had a strong disintegrating action. These were taken out and belt-conveyors installed instead. In the meantime a set of bins had been erected for the different constituents of the charge, the bins delivering by belts to a main conveyor-belt, the different materials being therefore distributed in thin superposed layers on this belt. Provision was also made for breaking up the coarse lumps of slime. The conveyor-belt delivered into an elevator, and this in turn to belt-conveyors that distributed the charge to the feed-hoppers over the machines. These hoppers delivered to short conveyor-belts which fed the machines as described above. The damping of the charge takes place during transit from bins to machines.

This system of mixing proved quite successful. The constituents of the charge were sufficiently blended and the slime granules remained so far undisintegrated that the charge remained evenly open. A gratifying feature of this improved distribution of the charge on the machine was the evenness of the roasting mass. Blow-holes and other irregularities became more and more rare, and with this came a substantial diminution in the amount of metal lost by volatilization. In the roaster-charge there is always more or less of a roast reaction going on with production of metallic lead and a lead-sulphate fume. The more even conditions can be kept on the machine the more easy it is to control this, and consequently loss by volatilization has sunk to less than 1% of the lead on the pre-roasting machines.

The next step was the elimination of the Ropp roasters, Dwight-Lloyd machines being used to pre-roast for the Huntington-Heberlein pots. The same precautions were used in both cases, and the work correspondingly improved. At this stage, then, the roasting of the concentrate had become considerably simplified, the practice being:

- (1) All concentrate pre-roasted on Dwight-Lloyd machines.
- (2) All pre-roasted material crushed and the roasting finished either on another set of Dwight-Lloyd machines or in Huntington-Heberlein pots.

The following figures will serve to illustrate the practice which we had reached at this stage:

Average composition of charge to pre-roasters:

	%
Granular concentrate	49.0
Slime concentrate	18.5
Silicious ore	12.0
Limestone	6.0
Ironstone	14.5

This charge after complete roasting gave a sinter, of which the following is an average analysis:

	%
Lead	44 to 45
Zinc	5 " 6
Silica	9 " 10
Ferrous oxide	16 " 18
Manganese oxide	3 " 4
Lime	4 " 5
Sulphur	2 " 3

In many respects this sinter was satisfactory. Considering its high metallic content its sulphur was low, and it gave good results on the blast-furnaces, with no additions except a little limestone, particularly that which was finished on the Huntington-Heberlein pots. That which was finished on the Dwight-Lloyd machines was still rather weak structurally. The output per machine was good, the pre-roasting machines, which measured 21 ft. by 3 ft. 6 in. over the wind-box, dealing with 130 tons of concentrate per 24 hours.

There were, however, certain unsatisfactory features. In the first place the ironstone added passed into the blast-furnace slag and became a total loss. So also did the lime and the zinc, the percentage of the latter metal in the slag being too low to render its recovery economical. Further, attempts to raise the lead content of the

work which has been done with a view to elucidate its constitution will be described later in this paper.

From the point of view of roasting, however, here was a material carrying silica, lime, and iron-oxide, all of which we were adding to our roaster-charges. From the results obtained when trying out the different sizes of material it looked as though these substances became active when actually in a state of semi-fusion with the sulphides in the charge. Why, therefore, should not the slag act as substitute? True, the zinc content of the charge would rise owing to zinc brought into it in the slag, and this might possibly upset the blast-furnace running. On the other hand, we had become by this time pretty thoroughly convinced that zinc is only detrimental when sulphur is present in serious amount, and we looked to the slag to give us as good a roast in respect to sulphur-

THE PROPRIETARY MINE AND MILL AT BROKEN HILL

sinter were not successful, because it was not found possible to reduce sufficiently the percentage of sulphur in the finished sinter if the lead were seriously increased. By comparing the lead content of the sinter with that of the concentrate given above, it will be seen that the dilution is substantial. We were therefore on the lookout for some way of getting over these drawbacks, and the application of blast-furnace slag as an addition-agent in place of ironstone appeared to be worth trying.

The slag yielded by the blast-furnaces working on this class of sinter is rather a curious product so far as composition goes, as the following analysis indicates:

	%
Silica	21.0
Ferrous oxide	33.5
Manganese oxide	4.5
Lime	14.0
Zinc oxide	13.5
Lead	2.0
Silver	0.75 oz.

This highly basic mixture resisted all attempts to fit it into a formula which would satisfy any of the silicates usually postulated for lead blast-furnace slags, and the

elimination as the ironstone charge. In any case, if it did not—that finished the matter. Lastly, we looked to the slag to increase the strength of the Dwight-Lloyd sinter owing to its fusibility.

Trials with crushed slag were a failure. The stuff was hard to crush and gave us coarse pieces at one end of the scale and powder at the other, neither of which was desirable. Granulating the slag by pouring it into a stream of water yielded a mass of granules, these granules being much fissured and porous, and ranging from about 1/4 in. diam. down to 1/16 in., the majority of the stuff being around 1/8 in. With this material we soon began to get results. Encouraging results were obtained on the small scale, and finally the following charge was sent to the roasting-machines. The old charge is shown beside it for comparison:

	Slag charge, %	Old charge, %
Granulated concentrate	40.0	49.0
Slime concentrate	25.5	18.5
Silicious ore	10.0	12.0
Limestone sand	8.0	6.0
Ironstone	4.5	14.5
Granulated slag	10.0	...

This charge yielded a roasted sinter of the following composition (the old sinter is shown again for comparison):

	Granulated slag sinter, %	Old sinter, %
Lead	44.5	44.5
Zinc	7.5	5.5
Silica	11.5	9.5
Ferrous oxide	12.0	16.5
Manganese oxide	3.5	3.5
Lime	5.5	4.5
Sulphur	2.5	2.5

The sulphur content in both cases is good. The zinc has increased as was to be expected and the ferrous oxide has decreased. The blast-furnace behaved well on this sinter and we felt encouraged to go further. We accordingly changed to the following charge:

	%
Granulated concentrate	47.0
Slime concentrate	27.5
Limestone sand	7.0
Ironstone	4.0
Slag	12.5
Sand (silica)	2.0

It will be noticed that no silicious ore was used, this constituent being temporarily unavailable. The charge roasted well and gave no trouble. The analysis of the sinter showed:

Lead	47.5 to 48.5
Zinc	7.5
Silica	8.0 to 8.5
Ferrous oxide	13.0 to 14.0
Manganese oxide	3.0
Lime	5.5 to 6.0
Sulphur	2.5 to 3.0

The lead content went up without causing trouble and later we had no difficulty in carrying it as high as 50%. The blast-furnaces behaved all right, the slag showing:

	%
Silica	20.5
Ferrous oxide	30.0
Manganese oxide	4.5
Lime	12.0
Zinc oxide	19.0

Finally, the whole of the ironstone was taken off the charge. No trouble followed, and the charge became simply a mixture of ores, granulated slag, and about 7% of limestone sand. All crushing of raw materials was eliminated and the whole process simplified until a steady practice has resulted with corresponding beneficial effect on the blast-furnace operation which follows it.

Before leaving the subject of roasting, I should like to refer briefly to our more recent work on the blast-roasting of zinc concentrate. We were faced in 1917 with the urgent need of quickly increasing our zinc-concentrate roasting capacity, while anything like prompt delivery of roasting equipment was out of the question.

Blast-roasting on Dwight-Lloyd machines or Huntington-Heberlein pots of Broken Hill zinc concentrates was found to be out of the question owing to the high temperature generated and the fusibility of the ore, which caused it to melt and become impervious to the draft;

and having regard to the fact that the roasted ore was to be treated in retorts no addition-agents were possible. Finally, the problem was solved by pre-roasting the ore from 30% sulphur to 9% in reverberatories, at which point the heat generated on the blast-roaster is not sufficient to cause fusion, and finishing on a Dwight-Lloyd machine. The product is a dry crumbly sinter, readily broken through a $\frac{3}{8}$ -in. ring, at which size it is charged into the retorts where it works excellently, the sulphur content of the roasted ore being 1%. Recent work has shown that the capacity of a reverberatory furnace roasting our concentrate from 30% to 9% is rather more than double its capacity when roasting to 2%. Further, that, using a multiple-hearth muffled roaster, 5% of fuel is ample to bring the ore down to 9% sulphur. The blast-roaster requires not more than 1% of fuel to ignite the charge. Hence the consumption of coal by this method is reduced to a maximum of 6%. Further, an interesting relation has been established between the different factors concerned in roasting. These factors are three in number, namely:

- (1) Temperature.
- (2) Time.
- (3) Ventilation.

By 'ventilation' I mean the maintenance of contact between the ore particles and the air. These factors are more or less interdependent. For example, by increasing the length of time a lower temperature can be used. Our more recent work has shown that the factor of ventilation is of enormous importance.

In blast-roasting the air is drawn directly through the charge, and in consequence has an excellent chance to come in contact with the ore-particles. When roasting on a hearth the air passes over the charge, and, in consequence the contact between ore and air is poor, and the interstices of the ore-charge are largely filled with a mixture of sulphur di-oxide and nitrogen. This is to some extent shaken out during stirring, but as the stirring mechanism does not work in between the grains of ore the effect is incomplete. Moreover sulphur di-oxide being a dense gas has a low diffusion rate.

Consider first a furnace of the superposed-hearth type, namely, the M. & H., having two sets of hearths measuring 80 by 6 ft. The ore descends from hearth to hearth, and in general not less than the last two hearths will assist in eliminating the last 8 units of sulphur driven off. The capacity of the furnace is 40 tons of ore per 24 hours for the two sets of hearths. Consequently four hearths out of the fourteen are concerned with the elimination of the last 8 units of sulphur from 40 tons of ore. The hearths measure 60 ft. net between drop holes. Hence the total hearth area concerned in removing these 8 units from 40 tons of ore is 60 by 6 ft. by 4 = 1440 sq. ft. 8% of 40 tons = 7168 lb. sulphur. Hence amount of sulphur roasted off per square foot of hearth per day is five pounds.

The Dwight-Lloyd roaster we are using has an active grate area over the wind-box of 16 ft. by 2 ft. 6 in. = 40 sq. ft. and roasts 60 tons of ore from 9% to 1% per 24

hours. Hence the elimination of sulphur per square foot per 24 hours amounts to 270 lb. This is a remarkable result, and illustrates strikingly the tremendous importance of the ventilation factor. The ore passes over the machine in a layer from $\frac{1}{4}$ to $\frac{1}{2}$ in. thick, and the time required to eliminate eight units of sulphur is 14 minutes as against 14 hours or more for the M. & H. furnace.

I feel pretty well convinced that the future of zinc-concentrate roasting lies in a combination of multiple-hearth pre-roasters and finishing blast-roasters. The blast-furnace practice has undergone an evolution parallel to that of the roasting, and for the proper understanding of it some reference to the part played by zinc in lead blast-furnace troubles is essential. About seven years ago, I was engaged in an attempt to make use of a water-jacket blast-furnace for the production of zinc-oxide from low-grade zinc-carbonate and zinc-silicate ores. In the early stages of the work, before the conditions under which the zinc could be reduced and driven off from the charge were understood, from 70 to 80% of the zinc passed into the slag, which carried as much as 32% zinc oxide. In spite of the evil reputation which zinc possessed for making slag viscous and sticky, this slag ran perfectly and gave not the slightest trouble.

Zinc is only a trouble-maker when combined with sulphur. In the ore referred to in the preceding paragraph, the sulphur content was less than 1%. But with the high-sulphur sinters, which were the rule at Port Pirie before the reform of the roasting-practice, troubles due to zinc were serious and frequent.

Briefly, the trouble caused by zinc in the presence of sulphur is the formation of a zincy matte containing about 14% of zinc. This matte is of a mushy consistence and lends itself excellently to the building up of accretions inside the furnace. There is considerable evidence that it is soluble in the slag but separates out readily if the temperature falls. For example, it forms a crust on the surface of the slag in the slag-pots, having apparently separated from solution and come to the surface. Its constitution and properties need more thorough study than they have received in the past.

The introduction of slime concentrate into the charge had increased the zinc content and at the same time, before the roasting of the slime had been properly worked out, had brought up the sulphur content of the sinter likewise. Hence conditions were well adapted for trouble in the blast-furnaces. A rather curious practice had developed. Large bodies of old slag running lower in zinc than the new slag were available on the dump. This material was quarried and charged into the furnaces. Enormous quantities were used, the old slag being from one to two times the weight of the other constituents of the charge. The furnaces were thus exposed to a tremendous flushing action by this mass of molten material passing through them, and in all probability, this slag also acted by dissolving the zincy matte produced from the high-sulphur sinter and carrying it out of the furnace.

This practice had several obvious drawbacks. In the first place the cost of quarrying was an item of expense,

and the disposal of this great volume of slag was another. Then again the melting of all this slag and its elevation to the temperature of the furnace consumed a good deal of coke, and the slag took up room in the furnace that could be more profitably occupied by sinter.

On the other hand it was felt by all engaged on the work that the true solution of the problem lay in the improvement of the roasting, and that no attempt should be made to seek out remedies for the blast-furnace troubles until sinter of reasonably low-sulphur content was available. As improvement in roasting continued, the blast-furnace practice was modified until it became simplified down to its present form.

In the days of the returned-slag practice the charge was a complex one, consisting of:

Dwight-Lloyd sinter,
Huntington-Heberlein sinter,
Ironstone,
Limestone,
Refinery-drosses,
Returned slag,
Slag shells.

The last item is the slag which is frozen in the pots and forms a shell or skull. The metal in the slag tends to concentrate in these shells and they are consequently returned to the furnaces.

Since the introduction of granulated slag into the roaster-charge the blast-furnace charge has become:

Dwight-Lloyd sinter,
Huntington-Heberlein sinter,
Refinery drosses,
Slag shells.

The simplification is obvious. The furnaces are hot, run smoothly, and the slags are low in lead (1 to 2%). The surface of the slag in the pots is free from any crust of zincy matte.

In this connection it may be pointed out that the Broken Hill ores contain less than 1% copper. Where copper in oxidized form is added to the charge, its high affinity for sulphur enables it to combine with this element to form an easily fusible matte which separates readily from the slag, or, as the furnace-men say, the copper cleans the slag. Where copper is present in serious amount higher sulphur can be carried without trouble, but with our ores 2.5% sulphur in a sinter carrying 45 to 50% lead is as much as can be allowed if perfectly smooth running of the blast-furnaces is to be assured.

The slag presents some interesting problems. The following analyses show the composition of the slag when ironstone to the extent of 14% was used in the roaster-charge, and again after granulated slag had been substituted for all the ironstone.

	Ironstone, %	Granulated slag, %
Silica	21.0	24.2
Ferrous oxide	33.5	25.6
Manganese oxide	4.5	5.3
Lime	14.0	11.0
Zinc oxide	13.5	20.0

In addition we have another one made when furnaces were running on a very zincy concentrate:

	%
Silica	18.3
Ferrous oxide	20.3
Manganese oxide	4.9
Lime	9.0
Zinc oxide	31.8

The difference between the foregoing figures and 100 is accounted for by alumina 5 to 6%, lead 1 to 2%, and sulphur 2 to 3%.

The ratios of bases to silica are for the three slags respectively 2.7, 2.17, and 2.96. In the last example the zinc oxide alone is more than sufficient to form with the silica a metasilicate. A good deal of work has been done on this slag with the object of working out its constitution. This is not yet complete but the results obtained so far are of interest. Unfortunately there are no means at our disposal for ascertaining the constitution of a slag at the really interesting stage of its career, namely, while it is still in the furnace. Once safely out of the furnace its practical interest has largely departed. Still a certain amount of information can be obtained from the frozen material.

In thin slices under the microscope the slag is seen to consist of two distinct mineralogical types, namely, a clear and transparent ground-mass, with a black to brown, opaque to translucent, scattered constituent. In the former olivene (fayalite) and willemite (the orthosilicate of zinc) are present. The brown mineral has been provisionally determined as a zinc and iron-bearing spinel or ferrite. Crystals of the green zinc-alumina spinel are also present.

The evidence in favor of the presence of iron-bearing spinel is as follows: In fine powder the slag is decidedly magnetic, and if kept melted for some hours at a temperature close to its melting-point it deposits a strongly magnetic mushy material. The natural ferrite or franklinite is strongly magnetic. Its crystallization, though not very distinct, is apparently octahedral. It is well known that zinc ferrite is insoluble in dilute sulphuric acid. If the powdered slag is subjected to treatment with a substantial excess of this acid, only a part of the zinc is soluble, the remainder being retained in the dark-colored insoluble residue. Ferric oxide is present in the slag but its determination is difficult owing to the reducing action of sulphides in the slag.

In many cases the brown mineral is found in fine parallel rods in the silicate base, these rods being oriented according to the crystallization of the silicate ground mass in which they are embedded. The appearance suggests that they have been rejected from solution in the silicate at the moment of freezing. It would appear that some zinc oxide is present in solution also.

Provisionally then we regard the zinc as being distributed between the silica as a silicate and the iron as a ferrite, and that while the slag is in the furnace the latter is probably in solution in the former; and moreover that some part of the zinc is also in solution. That these compounds are perfectly fluid at the temperature of the

furnace, the smooth operation is sufficient proof.

It is hoped that as a result of the experimental work now going on we shall eventually be able to arrive at the true constitution of the slag. There is no doubt that the whole question of slags is worthy of more investigation than it has hitherto received.

Before leaving this subject, the possibility of recovering part of the zinc in the slag needs a few words. It would appear that our slag in the future will carry about 20% of zinc oxide, if not more. I have already referred to the fact that the earlier slags were too poor in zinc to make the recovery of this metal worth while. With 20% or more of zinc oxide, the question takes on a different complexion, and I believe that a large part of this can be economically recovered, either by blast-treatment or in a reverberatory furnace.

Reference has been made, under the head of roasting, to two types of sinter, namely, that made entirely on Dwight-Lloyd machines and that made in Huntington-Heberlein pots after pre-roasting on a Dwight-Lloyd machine. Just which of these methods will finally be used, or whether both will be retained, is a question that cannot be answered yet. The Huntington-Heberlein sinter is still stronger than the Dwight-Lloyd, but less porous. The Huntington-Heberlein is more massive and stands rough-handling better. There seems to be little doubt that the blast-furnaces run better on a mixture than on Dwight-Lloyd alone, and, provided this is borne out by further testing, it is probable that both methods will be retained.

The foregoing covers the main elements in the development of our roasting and smelting practice. In general, we have moved along the line of simplification of methods, and so far as our opportunities and abilities lay have aimed to progress by way of making the best use of our existing equipment rather than by radical changes in it. In fact the great difficulty of obtaining supplies of this kind practically forced us to adopt the lines we did.

There is just one point I wish to make in this connection. New processes and new appliances usually have the advantage of the concentration of a great deal of energy and trained brains on their development, while the older methods have a tendency to degenerate into rule-of-thumb practice. One sometimes asks oneself what would happen to these older things if they were laid hold of and studied with the some zeal that is devoted to the new ones. So far as lead-smelting goes I do not think that the last word has yet been said in regard to the method of blast-roasting the ore and smelting the sinter in blast-furnaces.

THE OWNERS of asbestos mines near Paotingfu, Peking district, are seeking capital for the development of their properties. It is said that if Americans do not evince an interest the holders of the concessions will have to turn to the Japanese for assistance. The available monthly output is estimated at between 100 and 200 tons. Other deposits in the vicinity of Liangkochwang are for sale. The samples shown have a fibre of good length, of which about 30 tons monthly is available.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

PRODUCTION FROM CRIPPLE CREEK.

CRIPPLE CREEK.—Production during June from the Cripple Creek district totaled 38,867 tons, average assay-value \$13; and gross bullion, \$443,867. The Golden Cycle mill at Colorado Springs reported treatment of 18,500 tons of \$20 ore with value of \$370,000. The Portland company's Independence mill at Victor treated 19,667 tons of an average value of \$3.64, and the total bullion amounted to \$71,765. Samplers shipped 750 tons to smelters estimated at \$75 per ton. The Portland Gold Mining Co. has declared the regular quarterly dividend of 1½c. per share; payable July 20 to stock of record July 13. This amounts to \$45,000 and will bring the total to \$11,647,080.

The Wilson lease is again shipping from the Ingham mine on Raven hill owned by the Doctor-Jack Pot Mining Co. The ore is milling grade. A new and rich ore-shoot has been opened on the 14th level of the Dexter mine on the south slope of Bull hill, on the Trail property of the United Gold Mines Co. by the leasing firm of Anderson & Benkelman. The vein, 4 to 5 ft. wide, is reported to carry rich ore. The extent of the shoot is not yet determined. Ore will be shipped from the War Eagle workings at the Moffat tunnel level, during the ensuing week. The ore will be hoisted through the Blue Flag shaft. Development at the 1200 and 1400-ft. levels of the Blue Flag continues.

Dumps at the Index mine, Gold hill, are to be worked over and screened. Ore saved will be shipped to the Golden Cycle mill. Delay has arisen in starting up the Gasche process mill of the Lincoln Mines & Reduction Co., on Ironclad hill, because of the failure of the manufacturer to ship minor parts of machinery.

IDAHO SPRINGS.—Boston owners of the French Flag, closed down when Col. Ripley, the manager, entered the coast-defense service during the War, are preparing to resume operations. The Roosevelt Mining & Milling Co. has resumed operations on its properties at Alice. The Metals Mining & Leasing Co. has installed machinery at the Big Five tunnel and is cross-cutting to cut the extension of the Comstock shoot on the Sheffer claim. The Lincoln group is under development through the Big Five tunnel by B. F. Zalinger of New York, B. F. Francis, and Denver associates. A flat vein 40 in. thick and of good ore is reported opened up on the Virginia B. on Bellevue mountain.

EMPIRE.—The Golden Empire Mining Co., that is op-

erating the Conqueror, Union, and General Harrison, in North Empire, and the Tennessee, Denver City, and Marshall-Russell groups on Covide mountain and Miller gulch, and that controls a large group of some 200 claims in the district, will shortly commence shipments. A modern mill has been constructed and is turning out concentrate. Three other mills on the property are to be remodeled. Shipment of a good grade of ore mined by lessees from the Bellevue-Hudson is being made regularly. The leasing firm of Nelson & Co. is shipping to the Idaho Springs mill and Pueblo smelter of the American Smelting & Refining Co. from Silver Mountain properties.

CENTRAL CITY.—Denver operators have taken over the Federal mine in Russell gulch under bond and lease and are preparing to develop it. The shaft is 400 ft. deep and produced rich ore when last operated. Water in the Coaley shaft in Silver gulch has been lowered several hundred feet. The shaft is 800 ft. deep and through long inactivity is in such condition that it must be re-timbered. The mine, now operated by the O. C. Reddick company, was one of the first silver producers in Gilpin county.

MONTANA

BUTTE AND PLUTUS SHAFT CUTS WIDE VEIN OF SILVER ORE.

BUTTE.—Six feet of silver ore has been cut by the Butte & Plutus company while sinking its shaft. The discovery was made 250 ft. from the surface and is believed to be the Plutus main vein. Exploration of this vein will be continued from the 300-ft. level. When the shaft reaches the 400-ft. level, a cross-cut will be run toward the Norwich claim to intersect the south-dipping Norwich vein. The orebody consists of silver sulphide with a pink manganese gangue.

COOKE CITY.—A fleet of twenty 2½-ton trucks is being used to haul the ore from this district to Gardner for shipment by rail. A temporary loading-station has been constructed until permanent ore-bins are built. The Republic mines expect to ship 50 tons per day by truck. W. E. Renshaw has charge of the development work for the Republic interests.

NEIHART.—W. D. Murphy and H. Westgard have leased the Rochester mine from the Cascade Silver Mines & Mills Co. for a period of six months. A steam-plant, compressor, and other machinery have been installed to speed-up development work. A promising vein has been uncovered.

The Flohart Silver mines, which were closed down on account of the O. B. U. strike for four weeks, resumed

operations for one day, only to close down again the following day. The men had agreed to accept the terms of the management, but the agitators succeeded in persuading them not to. The scale agreed to was as follows: Blacksmiths, \$6.50; compressor-men, \$5.75; blacksmith helpers, \$5.50; machine-men, \$5.50; carpenters, \$5.50; shovelers, \$5; and laborers, \$5. The O. B. U. was not to be recognized, and there was to be no discrimination.

BOULDER.—High-grade copper ore has been found at the Shields and Ironside mine at a depth of 800 ft. The ore assays \$42 per ton across the face of the vein. M. L. Leydig of Helena holds the property under lease and bond.

NEVADA

LOW-GRADE VEINS AT QUARTZ MOUNTAIN ARE TO BE DEVELOPED.

QUARTZ MOUNTAIN.—The Goldfield-Quartz Mountain Mining Corporation has been organized to develop the Bell group of eight gold claims at Quartz mountain, 12 miles west of Goldfield. The purchase price is said to have been between \$10,000 and \$15,000. The company was financed in Los Angeles and all of the officers are Los Angeles men. Corrin Barnes of Goldfield is consulting engineer. Air-drills will be used to extend a 160-ft. tunnel 65 ft. to cut the vein at a depth of 140 ft. The vein is 110 ft. wide, consisting of four bands: A 20-ft. width of iron-stained porous quartz; 40 ft. of pumiceous material; 30 ft. of hard dense quartz; and 20 ft. of iron-stained material. The ore is in the iron-stained and pumiceous bands, but pannings can be secured over the entire width of the vein. The following assays were secured: An 8-ft. width, \$8; 18 ft., \$17; 24 ft., \$5.20. The gold, yellow and high-grade, is in flakes embedded in quartz. The vein follows the general course of the fissuring in the district. The outcrop is 1500 ft. long, conforming to the curvature of the hill known as Quartz mountain, and the silicification becomes less intense from the top of the hill, the vein being composed of softer rock where it disappears under the wash of the slopes. Mr. Barnes says the surrounding formation is dacite and that the hill is "an effusive mass of material similar to the dacite and erupted at a slightly later time". He says it probably is allied to the dacite vitrophyre of Ransome's report on the Goldfield district. Some of the fissures are large and show the result of displacement. Some are completely filled with quartz and others are open, forming crevices.

TULE CANYON.—A contract has been let to sink 100 ft., from the present depth of 150, the Silver Hills shaft in Tule canyon. The Silver Hills is operating the Ingalls mine under option. The company will pay \$20 per foot and furnish power.

STONEWALL.—The Yellow Tiger, which is driving a tunnel at Stonewall mountain, near Goldfield, has levied assessment No. 2, at the rate of one cent per share, payable immediately and delinquent August 7. The company collected \$25,400 by assessment No. 1, levied December 8, 1919, and to June 15, \$20,450 was spent, leav-

ing a balance of nearly \$5000. There was spent for the erection of buildings at the mine, for road-construction and machinery \$8300; a \$3000 payment was made on the Red Lion claims at Goldfield; office, corporation, and administration expense was \$2600, and labor and supplies cost \$2400. The clearing of old accounts, prospecting at Goldfield, and the purchase of equipment for the tunnel and a motor-truck made the expenses heavy.

MONTEZUMA.—The Harmill has completed several buildings on the Monitor claims and has built a road to the shaft. A new hoist-house has been built and a 15-hp. hoist is to be moved from Divide, which has become a good field for the purchase of second-hand machinery, as Goldfield long has been for houses. During the height of the Divide boom there was never a day for months that there was not a house on the road from Goldfield to Divide and now all of them, except those at the Tonopah Divide and a few other places, have little more value than the claims on which they stand.

TONOPAH.—The Tonopah Extension has moved 10 houses from Goldfield and has furnished them with modern conveniences. They will be rented to employees at a low rate in an effort to solve the miner-shortage problem, which has become acute in some southern Nevada districts. The labor turn-over in the smaller districts is heavy and the shortage of good miners is felt keenly. An engineer in charge of a dozen prospects in southern districts complains that he cannot secure good miners and says his experience in the last year leads him to believe the 'mucker' is entering the class of the dodo.

JUNGO.—Three leases have been let by the newly organized Pershing Lead-Silver Mines Co. on the claims owned by the company at Jungo, in Pershing county, three miles from Antelope on the Western Pacific railroad. The Pershing Lead-Silver is sinking a shaft, now 40 ft. deep, in ore from a few inches to three feet wide and assaying \$35 to \$40 in lead, silver, and gold. Jungo is one of several districts in or near the Jackson range that have attracted attention in recent months. The Mandalay is sinking a shaft in silver-gold ore near the Pershing Lead-Silver. Work on a small scale for many years in the Jackson range has resulted in promising copper, gold, silver, and lead prospects, but important mines have not resulted. Several carloads of high-grade silver-sulphide ore have been shipped from the Mandalay and small shipments of rich silver ore have been made from the Duffner, 15 miles north of Jungo. Twenty miles from Jungo, at the southern end of the Jackson range, the Craven company has shipped high-grade copper ore and has concentrating ore blocked out to a depth of 200 feet.

GOLDFIELD.—The Silver Pick has started shipping to the Development mill at a rate of 25 tons of \$15 to \$18 ore daily. The shipments are being made from the 117-ft. level. The cross-cut at a depth of 271 ft. will have to be driven 80 ft. more to cut the same vein. All of this work is being done in ground sub-leased from the Development company.

TOLICHA.—A 10-ton pan-amalgamation plant has been

started at Tolicha to test ore from the Landmark claims, being developed by Thomas Harney of Chicago and associates. Two of four wide veins 5 to 20 ft. wide have been cut and the value and width of the ore, as reported unofficially, indicates that a mine of much possibility is being developed. A tunnel is being driven and a 10-ft. width of ore assaying more than \$100 is reported in the first vein cut. A 3½-ft. width is said to assay more than \$500. Mr. Harney, who makes his headquarters in Goldfield, has consistently refused to make a statement regarding the mine until further work has been done.

UTAH

DIVIDENDS OF UTAH MINING COMPANIES.

SALT LAKE CITY. In spite of unfavorable conditions, the metal mines of Utah showed a gain in the amount of dividend disbursements for the first six months of the current year, as compared with the same period for 1919, amounting to \$120,083. During the first half of 1919 the Bingham Mines Co. and the Ontario Silver company paid dividends, whereas so far this year they have paid none. The Daly-West, of Park City, has been added to the list of dividend-payers this year, after a period of seven years. The following table shows the disbursements for the first half of 1920 and 1919:

	First half of 1920	First half of 1919
Bingham Mines Co. (Bingham).....\$	\$75,000
Chief. Con. Mining Co. (Tintic)....	176,846	169,004
Daly Mining Co. (Park City).....	45,000	52,000
Daly-West (Park City).....	100,000
Eagle & Blue Bell (Tintic).....	89,314	44,657
Grand Central Mining Co. (Tintic) ..	42,000	24,000
Iron Blossom Mining Co. (Tintic) ..	25,000	25,000
Judge M. & S. Co. (Park City).....	120,000	60,000
Ontario Silver (Park City).....	75,000
Tintic Standard (Tintic).....	234,540	187,952
Utah Copper Co. (Bingham).....	4,873,470	4,873,470
Total	\$5,706,171	\$5,586,083

In addition to this, the American Smelting & Refining Co. and the United States Smelting, Refining & Mining Co., both with extensive interests in the State, have paid dividends, part of which were earned in Utah.

EUREKA.—In spite of the railway embargoes, lack of miners, and unfavorable conditions that have prevailed at various times during the first six months of 1920, ore shipments from the Tintic district during that period totalled 3537 cars, as against 3632 for the same period in 1919, or a decrease of but 95 cars. Mining in this district was started in 1870, or exactly a half-century ago. The camp has been a steady producer during all this period, and shipments today are at the rate of about 600 cars per month. So far this year, five new shippers have been added to the list of producers. Ore shipments from the camp for the week ended July 3 totalled 148 cars, or one less than for the previous week.

Directors of the Chief Consolidated have declared a dividend of 10c. per share, payable August 2 to stockholders of record July 10. This payment, the second quarterly for the current year, will call for \$88,423 and

will bring the grand total dividend disbursements by the company up to \$1,783,094. A new co-operative leasing system is being tried out by the company. Slopes of liberal size are turned over to a group of miners on a royalty basis, which ensures the company about the same amount of money that could be realized under the old system of 'company time' work, and at the same time gives the men employed a chance for a greater return for their labor. In a few places this plan is being tried out below the water-level, where three shifts are required, and this means that as many as ten or twelve miners share in the revenue derived from a single block of

NEVADA CON. PIT, COPPER FLAT, NEAR RUTH

ground. The regulations governing this system of leasing require that every miner who works on the block be interested, and when the work of any man becomes unsatisfactory, his partners in the lease have the right to vote him out and take in another miner. As the lessees have not been to any expense in searching out the ore, or in putting it in shape for extraction, the company's royalty charges are necessarily larger than usual, but even so, there is more money to be made by the lessees as extra compensation for efficient work, over and above regular daily wages.

The Tintic Standard company shipped 100 carloads of ore in June, and this amount could be easily increased if men were available. The mine could use at least 100 more men. A part of the present output is from the deepest level (1450 ft.) where a large deposit was opened recently. In the south end of the property, three headings are

being driven, two on the 1200-ft. level and one on the 1000. One of the drifts on the 1200 is being sent over toward the big stopes, principally to help ventilation, although it should encounter ore. About 1200 ft. of work remains before the connection is made. E. J. Raddatz, president of the company, states that the claims of the South Lily Co. have recently been purchased by the Tintic Standard. The South Lily adjoins the Tintic Standard on the south. Excellent progress is being made on the new milling plant, and it is expected that the first unit will be ready for operation by fall.

PARK CITY.—Shipments for the first six months of 1920 were about 50% larger than for the corresponding period of 1919, being 52,443 tons as against 35,368 tons. The high price of silver during the early part of the current year stimulated mining considerably, which accounts for the increased production.

The Judge M. & S. Co. will open a company store that will be ready for business on August 1. The store will be conducted solely for the benefit of the employees of the Judge company and all other properties under the same management. All goods will be sold on the cost system. Coupon books will be issued to the employees, and if unused coupons are in possession of employees when connection is severed with the company, they will be redeemed at full value. The store will be open every afternoon and goods delivered once each week, purchasers paying pro-rata the expense of delivery.

An important strike of high-grade ore was made recently in a cross-cut on the 700-ft. level at the Naildriver property, according to J. D. Fisher, superintendent. The ore has been developed to a width of three feet, and assays run as high as 150 oz. silver per ton. Shipments have been started, and should average 200 tons per week during the present summer. Frank Fleishman, superintendent of the Ontario, states that development work at that property was suspended for a week on account of the compressor breaking down. Operations were resumed on July 6. At the Silver King Coalition property, 190 men are now on the payroll and at least 100 more could be used to advantage. Physical conditions at this property are excellent, and development work in new territory is reported as highly satisfactory.

WISCONSIN

ZINC AND LEAD MINING DURING JUNE.

Notwithstanding the fact that offerings for zinc ore remained low and that the price for lead ore had dropped considerably, the Wisconsin districts maintained uninterrupted operation all through the month of June, and good production resulted. High-grade zinc ore recovered at magnetic separating-plants was in good demand at the beginning of the month, on a range of prices running from \$48 to \$51 per ton. Premium-grade ore commanded even higher figures, but a recession in price came the second week, the base holding flat at \$48.50 per ton. At the close of the month, the base price for refinery blende stood at \$49 per ton, and while complaint was general that the price was not high enough to warrant profit-

taking operators held their working-forces together hoping for an upward turn. Low-grade zinc-ore producers received better offerings during the month and a considerable portion of reserve ore was sold but lean producers found it hard going and several mines were shut-down pending better market conditions. The mines in the Highland district operated by the New Jersey Zinc Co., were all shut-down and over 100 men thrown out of employment. Many quickly transferred to other parts of the field. The Blewett mine, in the Galena district, shut-down and several producers in the Livingston district gave up all hope of continuing production, assigning as the reason low prices for zinc concentrate.

Lead ore, which had reached \$110 per ton prior to June, dropped at the beginning of the month to \$100. This figure was destined to remain but a short time and the price current over the better part of the month ruled around \$90. Many producers who had refused \$110 for their ore, believing even better prices would prevail, held on after the drop calculating the price would recover but, when less than \$100 was offered, a portion of the holdings was sold. The increased output of zinc ore aided materially in an increased production of lead ore and the reserve in the field closely estimated at the close of the month, is in excess of 1000 tons. No competition was noticeable between buyers as had been the rule when lead ore ruled high and the major portion of lead ore sold through June went to the Federal Lead Co. Scores of lessees gophering old workings on a small scale met with poor success and sales of mixed lots for the month were negligible. The bulk of the lead ore recovered in the Wisconsin field will come in the future from the big zinc-mine operators.

Producers of carbonate-zinc ore, in the northern districts of the field, shut-down permanently. Prices for this class of ore have been steady and fair but the big deposits have been mined out and unless new exploration work determines new ranges in virgin soil this portion of the field will be abandoned.

Deliveries of zinc ore and lead for June, by districts, follow:

Districts	Zinc, lb.	Lead, lb.
Benton	10,360,000	440,000
Cuba City	4,600,000	62,000
Livingston	5,492,000	80,000
Galena	3,558,000	160,000
Day Siding	814,000	80,000
Highland	760,000
Hazel Green	806,000
Platteville	716,000
Shullsburg	664,000	90,000
Linden	336,000
Millbrig	132,000
Total	28,238,000	912,000

The gross recovery of crude concentrate for the month at mills amounted to 13,949 tons. A small surplus of crude ore was disposed of during June but the reserve in the field at the close of the month ran up near 10,000 tons, most of which was held at refineries and by one or two of the larger operating concerns.

Shipments of high-grade blende from separating-plants were made for the month as shown here.

Company	Lb.
Mineral Point Zinc Co.	5,670,000
National Ore Separators	2,966,000
Wisconsin Zinc Roasters	1,266,000
Block-House Mining Co.	540,000
Zinc Concentrating Co.	532,000
Total	10,974,000

The total net deliveries of high-grade zinc ore from the field to smelters for June amounted to 5487 tons of blende, and 440 tons of carbonate-zinc ore.

Raw-ore production was distributed as follows: to the Mineral Point Zinc Co., 5487 tons; Wisconsin Zinc Roasters, 5360 tons; National Ore Separators, 2147 tons; Zinc Concentrating Co., 685 tons. High-grade ore was divided mainly between the Prime Western Smelters, a subsidiary of the New Jersey Zinc Co., Depue, Illinois, and the Mineral Point Zinc Co., so that practically all went one way for the month. It indicates that the buying-latitude in the field is more closely restricted than ever before.

Labor conditions remain precarious. Shovelers especially were in demand, although the pay is the highest ever known and the men employed earn as high as \$10 to \$12 on a single shift. Some accidents were reported, one at the Jefferson mine, near Hazel Green, following a cave-in of supporting pillars resulting in the death of three miners. Exploration work in the field has been reduced considerably and at the end of the month little construction work was in progress in any of the districts.

BRITISH COLUMBIA

PORTLAND CANAL AND DOLLY VARDEN DISTRICTS ARE FLOURISHING.

WINDERMERE.—Construction of a second unit of the power-plant for the Florence mine, at Princess creek, is well under way. The company is employing 60 men, and working a double shift in the mine and a single one in the mill. About 150 tons of ore is being treated daily, and it is expected that over 300 tons of concentrate will be produced each month. The mine is in splendid condition, both the fissure and replacement veins yielding a good supply of ore. More miners are needed.

The Laib Brothers, who are operating the Spokane group, are crushing the ore in an arrastre and running the pulp over amalgamated copper plates, and tables. Most of the gold is collected in the arrastre and on the plates and the silver-lead concentrate is shipped to Trail. Transportation facilities are bad, the cost of shipping to the smelter running from \$50 to \$60 per ton.

PRINCETON.—E. T. Hodge, late professor of mining at the University of British Columbia, has bonded the Emancipation group of eight claims, at Jassica, 15 miles from Hope. Some good ore was taken from this property in 1916 by C. H. Lighthall, who had an option on the property, 53 tons yielding \$18,295. Later in the same year F. Merrick netted \$2822 from eight tons of ore shipped to the smelter. D. C. Coleman, president of the Canada Copper Corporation, has announced that the

railway from Princeton to Copper Mountain should be finished by September 1, and the corporation expects to start milling on that date. The West Kootenay Power & Light Co. has nearly completed its 115-mile high-power branch to the property.

STEWART.—It is declared that there is no mining boom in the Portland Canal district, but that there is much solid development. Nine diamond-drills now are in operation, two on the Premier, two on the Northern Light group, one each on the 49 group, the Big Missouri, the Mother Lode, Goose Creek, and the B. C. Exploration Co.'s property on Marmot river. It is stated that the snow is rapidly disappearing from the higher reaches and that there is still employment for good miners.

Activity is apparent through the country contiguous to the Bear River valley. Men are engaged in putting the line of the Canadian Northeastern railway, owned by Sir Donald Mann, in shape for operation, and a gas-locomotive has been bought, together with some rolling

TINTIC MILLING CO.'S PLANT AT SILVER CITY, UTAH

stock, in order that the transport of supplies to the various camps may be undertaken as soon as the repairs to the road render it feasible. On the Q. & L. group, held under bond by J. Tretheway, of Cobalt, surface-stripping has exposed a vein and a tunnel has exposed ore containing galena, zinc-blende, and silver.

ALICE ARM.—The population of the town of Alice Arm is growing to such an extent that much building is in progress. A three-story hotel is under construction in addition to numerous cabins. The community radiates prosperity. Everyone is busy and the Dolly Varden railway is operating regularly. Reports are received regarding the richness of the new ore being found in the Dolly Varden mine. It is stated also that the Royal group nearby is showing up well. Prospectors are going into the hills both up the Kitsault and the Illiance rivers.

USK.—High-grade copper ore is reported on Nicholson creek, near Usk, by Alexander Baxendale, a prospector. As a result the Crescent group of mineral claims has been staked. Stripping is said to disclose a fissure vein, one to six feet wide, for a distance of 700 ft. carrying bornite and chalcopyrite, much of which is rich enough to ship.

SLOCAN.—That the Utica mine will be re-opened at once and put on a shipping basis is announced by C. F.

Caldwell, vice-president and managing director of the Utica Mines Ltd. The old Sunset property, situated near the Utica, also is to be developed. The latter has not been worked for fifteen years. During its operation over \$500,000 worth of ore was shipped, some 2000 tons averaging over \$250 per ton at the former price of silver. It is proposed to continue the existing cross-cut to strike the vein at new depth.

NELSON.—Another deal is reported in connection with the Granite-Poorman mine, on Eagle creek, it being stated that a syndicate has been formed to take over the property from the Vincent Development Co. As a result the Granite-Poorman property will resume operation immediately, a crew of men already having been put to work.

ONTARIO

PROVINCIAL MINES DEPARTMENT TO BE INVESTIGATED.

TORONTO.—An investigation which has been for some time in progress into sales of timber by the former Provincial administration has resulted in the discovery of extensive frauds, occasioning considerable loss to the public treasury. As until recently the Department of Mines was included in the jurisdiction of the former Department of Lands, Forests, and Mines, it is suspected that a laxity of administration, if nothing worse, may have resulted in similar abuses in connection with mining sales or leases, and Premier Drury has announced that a thorough investigation of the Department of Mines will be held. In view of the facts as disclosed by the timber investigation, no other course appears open to the Government, and the action meets with general public approval.

PORCUPINE.—The shareholders of the Hollinger Consolidated have approved of the removal of the head office of the company from Toronto to Timmins. A contract has been let for diamond-drilling the Miracle property south of Night Hawk lake, the work to be started as soon as possible. It is planned to tap the main vein at 300 and 500 ft. The property, previous work on which yielded promising results, is equipped with a mining and a milling plant.

KIRKLAND LAKE.—At the Ontario Kirkland work has been started on the excavation for the mill. It is planned to have the foundations and perhaps the framework of the building completed before winter. Drifting on the 450-ft. level is being actively carried on, the ore being richer than on the upper levels. Operations at the Wright-Hargreaves have been handicapped owing to shortage of power. The main shaft was unwatered some weeks ago and work started, but it had to be abandoned through failure of the Northern Ontario Light & Power Co. to deliver enough electric energy. Steam-power is being used on shaft No. 2, which has been straightened and timbered to a depth of 200 ft. The foundations of the mill have been completed and work started on the building, which is expected to be finished and the machinery installed late this fall. The date for commencing milling operations has been indefinitely postponed owing to

the power shortage. A vein about 10 ft. wide has been opened on the Wood-Kirkland in a dike of porphyry formation stated to be about 400 ft. wide. Several veins have been uncovered by surface work on the Moffatt-Hall claims near Mud Lake. Trenching is being carried on to ascertain the best point for sinking. At the Chaput-Hughes the shaft is down 40 ft. on a 5-ft. vein, the gold content of which shows an increase at depth.

SESEKINIKIA.—On the Russell claims, adjoining the Smith-Labine group, a discovery regarded as being of importance has been made. Trenching has revealed a schistose zone, about 70 ft. wide, cut by numerous quartz stringers of low gold content. The quartz, which is highly enriched with pyrite, is blue in color and the stringers are usually narrow. The shaft on the Lightning River Gold Mines properties, $2\frac{1}{2}$ miles east of Sese-kinika Station, is down 20 ft., the vein showing improvement and maintaining its width.

COBALT.—During the first six months of 1920, the silver mines of Northern Ontario produced approximately \$6,372,000, according to preliminary estimates. This compares with \$12,747,621 for the whole of 1919 and shows how production is being maintained. The total silver output since the first discoveries in Cobalt in 1903, up to June 30 of 1920, amounts to 309,011,136 oz. valued at \$188,411,972. Dividends paid amount to some \$84,000,000, while the treasuries of the various companies contain upward of \$15,000,000, the net profit realized approximating 50% of the total production. The sixth high-grade ore-shoot to be opened since last fall is reported this week on the Beaver Consolidated. There is some promise of regular quarterly dividend disbursements.

The regular quarterly dividend of 5% declared by the Nipissing on July 20 is not accompanied with the usual bonus of equal amount. The company has quick liquid assets of over \$5,000,000, the highest figure in its history, and the failure to pay a July bonus is interpreted as indicating the intention of the directors to yield to the request of shareholders to distribute its surplus more freely among stockholders. It is believed this will take the form of a substantial capital reduction at intervals, in addition to regular dividends.

Arrangements are being made to diamond-drill the Mohawk-Cobalt property in the Mud Lake district. An investigation of the possibilities of the Belle-Ellen mine in South Lorrain is being made by M. J. O'Brien, Ltd., with a view to recovering cobalt from the large veins on the property. Another shipment of ten or eleven tons of high-grade ore has been made from the Castle property of the Trethewey company. The ore contains, on an average, 2000 oz. of silver per ton. Current production is adequate to pay expenses, in addition to carry on necessary development work. Announcement is made that the Kerr Lake Mining Co. has arranged a contract with the Dominion Reduction Co. to treat between 75,000 and 100,000 tons of low-grade mill-ore. The Kerr Lake company will itself continue to mine its medium and high-grade ore.

CHILE COPPER CO.

The Chile Copper Co.'s report for 1919 emphasizes that in spite of world-wide economic and social readjustment since the Armistice, the finances of the company have been well husbanded and operations singularly successful, considering conditions under which Chile is working.

"Upon signing of the Armistice," it adds, "large stocks of copper were left on the market and coincidentally sales for about four months practically ceased. This necessitated curtailment in production. For the year ended December 31, 1919, your company produced 38,359 tons, compared to 51,068 for 1918. Capacity of plant during 1919 was approximately 60,000 tons. in spite of small production for 1919 actual cash cost of producing this copper, including estimated cost of selling and delivering, was 13.01c. per pound, compared to 13.30c. for 1918. During 1919 Chilean exchange was more favorable than in 1918, which helped to reduce the cost of production. On the other hand, it is estimated that nearly all other factors entering cost of production were considerably higher in 1919 than in 1918."

For the year ended December 31, 1919, a deficit of \$2,290,658 after all charges and taxes, against a surplus of \$3,440,229 in 1918 is reported. The combined income account of Chile Copper Co. and Chile Exploration Co. follows:

	1919	1918	1917
Operating revenue	\$10,350,167	\$20,931,071	\$18,908,855
Operating costs	8,729,956	12,414,667	11,751,778
Operating gain	1,620,211	8,516,404	7,157,077
Miscellaneous income	868,877	437,263	649,294
Total income	2,489,088	8,953,667	7,806,371
Federal taxes and miscellaneous	395,556	776,995	505,233
Interest charges	2,823,043	2,422,419	1,860,525
Deficit	729,511	*5,754,253	*5,440,613
Plant superseded	65,639	41,441	1,026,586
Ore depletion	1,355,508	2,132,583	1,710,615
Amount of bond discount	140,000	140,000	105,000
Deficit	2,290,658	*3,440,229	*2,598,412

*Surplus.

ARIZONA

Bisbee.—The work of pouring concrete in the Dallas shaft of the Copper Queen branch of the Phelps Dodge Corporation is now under way. Eventually this will be the main hoisting shaft for the entire Copper Queen mine, and will replace the Sacramento, through which the ore is hoisted at present. Owing to steam-shovel operations, in the course of time the Sacramento will have to be abandoned as an operating shaft.

Maricopa County.—At the Mammoth mine, near Superstition mountain, on the road between Mesa and Roosevelt, application has been made for the establishment of a post-office, and the changing of the name to Youngville, after the chief operator and owner, George U. Young, former Secretary of State. It is reported that new equipment is being purchased and development work is planned on an extensive scale.

CALIFORNIA

Grass Valley.—With 80 stamps dropping on high-grade mill ore from Empire and Pennsylvania mines, the Empire Mines Co. is doing well despite high labor and operating costs. The mine force has been increased and development of new territory below the 4500-ft. level is proceeding satisfactorily. Opening of ore in new ground has been attended with encouraging results during the past year. In the

Pennsylvania property good ore is also being opened at depth. The output is sent to the Empire mill over an electric railway.—Excellent developments are reported at the North Star, Alcalde, and Boundary properties. The Central mill of the North Star company is running steadily on good ore from deep levels. Shoots of bonanza quartz continue to develop in the Alcalde and Boundary properties, and both mines promise to be consistent producers. At the Allison Ranch drifting is proceeding along the new-found Hartery vein, with indications pronounced good for development of a large orebody in virgin ground.

Portola.—Regular shipments of copper concentrate are going out from the flotation-plants of the Engels and Walker mines, with new developments adding to the present ore-reserves of both properties. Recent work in the Superior section of the Engels group has placed in sight some of the richest deposits ever found in this district, and the grade of ore going to the plant continues excellent. Activities at the Beardsley, Gruss, Trask & Coffey, Five Bears, Feather River, and several other properties continue. Practically every company reports development of additional ore, with new work materially extending the dimensions of the proved reserves.

IDAHO

Coeur d'Alene.—The mines of this district have paid in dividends in 35 years \$95,082,316, nearly half of this in the last seven years. At the present rate of earnings the \$100,000,000-mark will be passed next year. Dividends in the first six months of the present year were \$2,660,357, and will probably continue at about this rate. The individual companies paid: Bunker Hill & Sullivan, \$981,000; Hercules, estimated, \$500,000; Interstate-Callahan, \$373,300; Hecla, \$350,000; Federal, preferred, \$299,757; Caledonia, \$156,300.

A new vein of fine ore has been uncovered by the Columbus Mining Co. The vein is 13 ft. wide and its discovery follows continuous work for two years.—Raising is in progress from the main-tunnel level of the Nabob Consolidated mine. The raise has attained a height of 20 ft. and will be continued to the next level above, which is 220-ft. higher than the main tunnel. The work will be completed in six weeks.—The Orogrande Gold Mining Co., near Stites, has increased the capacity of its mill to 500 tons daily. The designed capacity was 300 tons. Changes and improvements have been made in the method of ore-dressing.

—Workings of the Baltimore vein of the Silver Triumph Mining Co. have been entered for the first time in 30 years. Ore containing 39 oz. silver per ton, 20% lead, and 18% zinc has been discovered 60 ft. from the surface. The old workings honeycomb the ground on two tunnel-levels. The orebody between the main-tunnel level and a point 150 ft. deeper is six feet wide and gives promise of a greater width.

The Tamarack & Custer Consolidated Mining Co. is producing crude ore and concentrate at the rate of 3500 tons per month. The net value of the ore is said to range from \$100 to \$125 per ton. The purchase of a tunnel that penetrates an adjoining property is under consideration. This tunnel attains greater depth than any on the Tamarack & Custer and is convenient to a mill. Its use by the Tamarack & Custer will reduce the cost of mining.

MISSOURI

Joplin.—The Iowa Mining Co. is erecting a mill on its lease on the Gilmore land, two miles south of Baxter Springs, and expects to have the plant in operation by September 1. The mill was formerly the old Oak Orchard, north of Joplin. It is of 150 tons capacity and is in good condition. It is equipped with gas-engines, which will be the motive power at the Iowa mine. Ben Hoskins, mill-builder of Baxter Springs, is in charge of the construction work. A feature of the plant is that the building will be covered with a new roof entirely of zinc. Zinc sheets will be used and so placed as to conform to the best methods of laying roofing of this kind, allowing for expansion and contraction.

The Iowa company has had many obstacles to overcome in the development of its mine. The lease is regarded as one of the richest in the district. Eighteen or nineteen holes were sunk in the prospecting and a fine body of ore blocked out. Spasmodic troubles with water delayed operations at times and just when everything seemed to be ready for a continuation of mine development a fire destroyed nearly everything at the plant. After re-building the engine-house and derrick, work was resumed underground and negotiations were started looking to the purchase of a mill.

NEVADA

Searchlight.—A. S. Gaines and Charles Johnson have found some fine ore on their lease on the 600-ft. level of the old Duplex mine. The find is said to be similar to that made about two months ago by Burdick and Perkins on the 500-ft. level of the Duplex. Burdick and Perkins are still mining ore worth about \$200 per ton and are shipping at the rate of a car every eight days. Gaines and Johnson expect to begin shipments at once.

UTAH

Grantsville.—Promising mineralization has been penetrated in the adit being driven at the 'L' Marie property to open at depth a shoot of good ore previously opened by a shallow shaft. This property is situated in the Free Coinage district, nine miles east of here. In the face of the tunnel, which is about 75 ft. from the portal, four inches of high-grade silver-lead ore, containing manganese and spar, has been cut.

Bingham.—Upper workings at the United States properties here are to be turned over to lessees, according to D. D. Muir, mine manager. The United States properties include the old Jordan and Galena mines, from which high-grade galena was mined in the early days.

Alta.—Since June 15, the South Hecla company has been shipping an average of one carload of ore per day, according to George H. Watson, general manager. At present 57 men are employed at the property, and twice that number could be used to advantage, if they were available. A similar shortage of men exists in the other mines in the district.

WASHINGTON

Stevens County.—The only mining company in Washington that is now paying dividends is the Electric Point which has made two disbursements this year and expects to continue its present rate of \$23,790 per quarter. The Northwest Magnesite Co. is making good profits but has not yet declared any dividends. The American Minerals Production Co., also a magnesite corporation, paid a dividend of \$30,000 in 1917 and may resume payments before long, in view of the present condition of the mine.

A concentrating plant has been erected at the Lead Trust mine and has started operation. The plant is of 75 tons daily capacity and designed to dress lead ore. Operations have disclosed ore 6 to 14 ft. wide on two levels. One level is 200 ft. above the mill and the other 350 ft., both being opened with adits.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. L. Sizer is in Arizona.

J. Power Hutchins writes from Italy.

W. Pellet-Harvey, of London, is at Vancouver.

A. Campbell, of Anaconda, visited Globe recently.

Algernon Del Mar, of Los Angeles, is at Alamos, Mexico.

Wilber Judson is on his way back to New York from San Francisco.

Charles Janin left Penang, Straits Settlements, for London on July 7.

E. O. Daue has returned to Bluefields, Nicaragua, from Easton, Pennsylvania.

William R. Bishop and F. L. Watson, of Lima, Peru, are visiting the South-West.

Frederick F. Ransom is doing geological work in the oil-fields near Santa Maria, California.

D. A. Lyon, supervisor of stations for the U. S. Bureau of Mines, was recently in San Francisco.

John Davenport, formerly of Boston, is at Wausau, Wisconsin, in care of the Wausau Abrasives Co.

Robert M. Hampton, of Tonopah, is now superintendent for the Utah Boston Development Co., at Bingham, Utah.

W. S. Hall, metallurgical engineer for the Chino Copper Co., at Hurley, New Mexico, is visiting metallurgical plants in Utah.

Paul T. Bruhl has left Thomson, Georgia, and is now with the New York & Honduras Rosario Mining Co., at San Juancito, Central America.

M. J. Finnegan, of Worcester, and E. L. Marsh, of Boston, who are interested in Nevada and Utah mining properties, were at Salt Lake City recently.

W. Prouty, geologist for the Old Dominion company at Globe, has been appointed chief geologist for the Copper Queen branch of the Phelps Dodge Corporation at Bisbee.

R. A. Sulliger has left the Estaca Mining Co., at Contra Estaca, Mexico, to take charge of the Delores Esperanza Co., at Delores. H. D. Hickie succeeds him as superintendent for the Estaca Mining Co.

M. J. Gavin, refinery engineer for the U. S. Bureau of Mines, with headquarters at Salt Lake City, visited the San Francisco office of the Bureau during June in connection with oil-shale development.

W. E. Dickson, assistant engineer, and R. R. Rowe, junior engineer of the U. S. Geological Survey at Salt Lake City, are at Wabaska, Nevada, installing a new recording-gauge station on the Walker river.

T. H. O'Brien, for twelve years manager for the Stag Canyon Fuel Co., at Dawson, New Mexico, a subsidiary of the Phelps Dodge Corporation, has been appointed general manager for the Inspiration Con. Copper Co. and also for the International Smelting Co.

Dewey, Strong & Townsend announce the entry of Capt. William A. Loftus, Thomas Castberg, James M. Abbott, and John H. Herring into the firm, which will be known as Dewey, Strong, Townsend & Loftus, with offices as heretofore in the Crocker building, San Francisco.

J. M. Hill, of the U. S. Geological Survey, has been transferred from Washington to the Survey's office in San Francisco, where he will be associated with Charles G. Yale. Mr. Hill's field of geological studies will include the Pacific Coast States and to some extent also Arizona and Nevada. The desirability of having a geologist attached to the San Francisco office has long been felt, for many requests for examination and report are received that cannot be met by sending a Federal geologist across the continent.

EASTERN METAL MARKET

(By wire from New York)

July 12.—Copper is quiet and strong. Lead is inactive but firm. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/4 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

FOREIGN VIEW OF THE PITTMAN ACT

The New York market for silver and the operation of the Pittman Act have been followed with interest by bankers and bullion dealers in Europe. Under influences tending to depress silver in world markets, such as Chinese selling and Continental selling of silver coins, Europe watched the price decline in this market well below the dollar mark, with the Pittman Act ineffectual for the time being. Now that the Treasury has found a means of putting the Pittman Act into operation, and thus stimulating the price even for foreign silver, practicability of the measure is still questioned by foreign dealers.

Advices to hand reflect views of foreign dealers on information that the Director of the Mint had revised its regulations regarding tender of silver of United States origin, although mixed with alien-produced silver in refining. Resultant stimulation of silver in New York by this means is regarded as rather artificial and as tending to be against commercial interests of United States citizens in settlement of trade obligations with China, or where debts are to be paid in silver.

Samuel Montagu & Co., bullion dealers, of London, say: "There are two good reasons, both touching the well-being of the people of the United States, why silver sold under the Pittman Act should not be purchased at a dollar fine ounce. First, there is the prospect that if the dollar limit were removed their silver could be acquired at a substantial discount of 25% or more under the dollar per fine ounce. Second, the balance of trade with China was against the United States to extent of \$14,684,000 in 1914 and in 1919 had increased to \$48,639,000 (nearly 3 1/2 times).

"Any fall in the price of silver must have material effect in reducing to people of the United States the cost of commodities from the Far East. In the above figures a fall of 50% in the price of silver would not only show an apparent gain of \$5,000,000 to people of the United States, but it would really mean many times more, for trading and manufacturing profits connected with raw material imported from China would be, to a large extent, proportionately lessened by a reduction of wholesale and retail prices."

TAXES AND NATIONAL DEBTS

Financiers of experience and vision continue to stress taxes and public debts as factors of the utmost importance financially. Otto H. Kahn thinks the excess profits tax is the source of much economic evil and gives excellent reasons for his belief. Another economist, who is not of the banking fraternity, thinks there is great danger of the world's gold reserves becoming inadequate, and suggests that gold and gold interest-bearing bonds be made the basis of the currency by Congress if a great crisis is to be averted owing to the deflation of credit just when inflation is needed, or later will be needed, by expanding business in this country and in Europe.

As to national debts there is perhaps less awe of the great indebtedness piled up since 1913. Everything is relative. Is Britain's present war debt any greater, relatively speaking than the four billions she owed at the end of the Napoleonic wars? It is not. Britain is a great many times richer than she was 124 years ago. If this is true of the English what is to be said of the war debt of the United States which country equally rich, though only half developed, has a war debt of \$30,000,000,000.

	Demand.....	3.44
Lire, cents:	Demand.....	6.86
Marks, cents:	Demand.....	2.84

Eastern Metal Market

New York, July 7.

The three-day holiday has not been a stimulus to an already rather lifeless market. Prices have, however, remained fairly strong.

Buying of copper is only moderate but prices are steady and unchanged.

Business in tin is confined to dealers and is light.

Demand for lead is small. Prices are firm but nominal.

The zinc market is stronger and prices are higher.

Antimony is unchanged and quiet.

IRON AND STEEL

Pig-iron output increased in June, showing that the net result of all the changes in the railroad situation was favorable. At 3,043,540 tons for the 30 days the daily average was 101,451 tons, a gain of about 5000 tons per day upon the May output, which was 2,985,682 tons for 31 days. May in turn showed a gain of 5000 tons per day over April. But the industry is still nearly 7500 tons below the peak reached in March when the daily average was 108,900 tons. The estimated capacity active at the opening of the month was 101,500 tons per day, against 98,350 tons for 295 furnaces on June 1.

The latest word from steel-producing centres, however, indicates a more unfavorable turn, within the week. The Commerce Commission order that open-top cars be sent to coal mines and the renewal of the order directing box-cars to grain-producing sections have left steel-mills so short of cars that there is increased talk of a suspension of operations for ten days or two weeks to permit of a clearing up of the desperate congestion.

While reports from the automobile industry have been unfavorable, two companies made records in June, one turning out 3500 cars per day and another 625 cars.

Cars bought by industrial companies have amounted to 6500 since May 1 and active inquiries will bring the total to 10,000.

COPPER

Conditions as to labor and transportation are not greatly altered. Demand continues light from domestic sources but buying for foreign shipment is good. There is more interest for forward shipment by domestic buyers, and sales have been made of both Lake and electrolytic copper, for forward as well as prompt and early delivery, on the basis of 19c., New York. Large producers are firm in their quotations of 19c. for both grades. The outside market is believed to have been pretty well cleaned out of speculative and cheap lots and is quoted at around 18.50c., New York, for early delivery.

Statistics regarding copper exports show that to June 1 these have been at the rate of 30,906 gross tons per month and that the average for the half year will probably be 30,000 tons per month. This compares with 19,000 tons per month in 1919 and 32,000 tons per month in 1913, the record before the War. Exports during the War were highest at 41,000 tons per month in 1917.

TIN

There has been no heavy buying in this market recently. Such as has been reported has been mostly on the part of dealers and has not exceeded 100 tons. Consumers are not interested. Dealers, however, appear to be optimistic about the future of prices and this is the reason for this activity, but there are, however, few sellers. Until Friday of last week there was almost no buying, but late that day a few dealers were buyers of future shipment at prices ranging from 47.75c. to 49c. and at the close 49.50c. was asked. Spot Straits tin is scarce and prices are nominal and fairly stiff,

closing on Friday at 50.25c., New York. Yesterday, however, the market was nominally lower at 48c., New York, due to a decline in London over the holiday from £273 per ton on July 2 to £259 yesterday.

Tin arrivals in June are reported to have been 4730 tons, of which 900 tons came in at Pacific ports. The amount of tin delivered into consumption in June was 6500 tons, of which 5600 was from Atlantic ports. The quantity in stocks and landing on June 30 was 3586 tons. Imports to July 1, this year, have been 27,743 tons, of which 20,820 tons was Straits tin. To July 1, 1919, the imports were only 6341 tons.

LEAD

The market is quiet and quotations are nominal. The undertone, however, is strong. There is a marked scarcity for certain positions. It is almost impossible to purchase prompt-shipment metal and spot delivery is scarce. There is, however, almost no demand for either position. There has been no change in the quotation of the American Smelting & Refining Co., which is 7.75c., St. Louis, or 8c., New York. An appraisal of the outside market is a guess, but it may be conservatively quoted as nominal at 8c., St. Louis, or 8.25c., New York. Quotations range up to 8.50c., New York.

ZINC

The market is stronger and prices are higher. This is due to three causes. One is the shutting-down of most of the mines in the Joplin district, due to labor troubles and the exodus of men to the farms. This will last a month at least and thus reduce the supply of ore. Another cause is a better inquiry from galvanizers and brass-makers, and the third reason is a stronger London market. Prime Western for early and third-quarter delivery is quoted at 7.85c., St. Louis, or 8.20c., New York, with fair inquiries reported.

ANTIMONY

Quotations are unchanged at 7.50c. to 7.75c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted in wholesale lots for early delivery at 33c., New York, by the leading interest and at 31.50c. by other sellers.

ORES

Tungsten: There is no life to the market and no features. Quotations are nominal at \$5.50 to \$15 per unit, depending on the grade, the quantity, and the delivery.

Ferro-tungsten and tungsten powder is quoted at 85c. to \$1.05 per pound of contained tungsten, f.o.b. makers' works.

Molybdenum: Conditions are unchanged with prices nominal at 75c. to 85c. per pound of MoS₂ in regular concentrate.

Manganese: The market is strong at 70c. to 75c. per unit for high-grade ore. A large consumer has contracted for 20,000 tons per month of Indian ore, deliveries commencing last month to continue one year. Imports in May were 56,586 tons, the largest for any month this year. The total for the 11 months to June 1 this year is 243,572 tons, against 444,902 tons to the same date in 1919.

Manganese-Iron Alloys: Demand is light and quotations are firm at \$200, delivered, for domestic alloy for last half, with \$195, seaboard, for a limited quantity of British alloy. The spot quotation is \$225, delivered. Imports of ferro-manganese in May were 3981 tons, or the largest in a year and a half. The total for the 11 months to June 1, 1920, has been 33,279 tons, as compared with 22,200 tons to June 1, 1919. The spiegeleisen market is strong but quiet at \$75, furnace.

INDUSTRIAL PROGRESS

A NEW TRACK-SCALE

By L. R. Boyer

A new track-scale embodying many new and exclusive features has been developed by E. & T. Fairbanks & Co., St. Johnsbury, Vermont, manufacturers of the well known Fairbanks scales. This was occasioned partly by new speci-

since the first were built nearly ninety years ago. The feature first noticed on looking at the accompanying illustration is the departure from the use of the customary I-section levers, and the consistent use of the double-web section throughout.

The scale is built in two capacities for light-duty service, or service where only a relatively small number of cars is

to be weighed. These have 60 and 75-ton sections and lengths of 50 ft., 56 ft., and 60 ft. effective weighing rail. For heavy service or where a large number of cars is to be weighed the scale will be built in 75 and 100-ton sections and in the same three lengths as above. The difference between the light-duty and heavy-duty scales is mainly in the loading per linear inch of knife-edge, this being 5000 lb. in the heavy-duty scales and 6000 lb. in the light-duty scales. The difference in allowable loading and the allowance of a higher multiple main lever in the light-duty scales serves to make somewhat lighter castings than are necessary in the heavy-duty scales.

The beam in keeping with the other parts of the scale is novel in design. A close study will reveal that this design includes well accepted principles essential to an accurate and durable mean and the difference in appearance from the conventional type of beam is due to a consistent use of these principles. It is of cast-iron with cross-section of inverted-U shape. This shape, besides giving the maximum rigidity, furnishes a housing over the balance-ball and track for carrying the poise. The notches are cut in a steel bar inserted in the bottom of the back web, which ensures that no dirt can fall and lodge in them. The type for printing weights on tickets is fastened on the bottom of the

front web where it is protected from damage.

The centre indicating poise suspended from three ball-bearing trolley-wheels runs smoothly upon a machined track housed inside the beam. Its exact weighing position is determined by a positive locking device of 30 or more teeth engaging the same number of notches of the beam. This locking device or pawl moves in vertical guides arranged to be always tight, to ensure a positive position of the poise. A convenient handle on the front of the poise

Construction of New Track-Scale

Newly-Designed Scale Beam

fications adopted jointly by the American Railway Association, the American Railway Engineering Association, and other organizations. These specifications make necessary such changes in the design of scales on the market up to this time, that the new scales in accord with them are not interchangeable with the old scales. While changes were being made that were sufficient to destroy the interchangeability of the new and old, it was decided to go further and remove incongruities in design that have been present in scales ever

serves to operate the pawl when turned in one direction and to print the tickets when turned in the other direction. The beam stand is of the upright pillar type with compensating steel bearing-blocks machined in.

Standard erection-plans have been drawn which incorporate the best recognized practice as to all details of installation. Wide pits afford ample room for installing the scale correctly as well as for convenient examination from time to time. The design of weigh-bridge, the mounting of dead-rail supports and fastening, the arrangement of weather guards, and all other details have been worked out carefully, with a view to obtaining the most economical way, consistent with accurate performance and at the same time, the lowest maintenance cost.

HOW THE MOTOR-TRUCK MAY RELIEVE CONGESTION AT FREIGHT TERMINALS

By R. E. Fulton

Freight congestion is, in reality, terminal congestion. The present railroad situation vividly demonstrates that the root of the much discussed railroad inadequacy lies more in the lack of proper terminal facilities than it does in the lack of freight-cars. It has further proved that the motor-truck, properly used in conjunction with railroad terminals, can relieve terminal congestion and increase the productivity of each unit of the railroads' rolling stock.

Although it is estimated that the railroads of this country now need 500,000 more freight-cars, it is obvious that, if this number of cars were put into service under existing terminal conditions, the confusion would only be increased. Unfortunately, the majority of railroad terminals were constructed in the days of horse-drawn highway transportation facilities, and no provision was made for the advent of the motor-truck. At that time it was necessary for the railroads to bring their freight within a radius of a day's team-haul of its final destination, a distance considerably less than can now be covered by a motor-truck. Cities have grown and traffic has increased, but the terminals have remained practically unchanged as far as distribution radius is concerned. It is a fact that the average freight-car travels only about six miles per day, and that this inefficiency can be attributed directly to wasted time through congestion at terminals. Considering that we now have over 2,400,000 freight-cars in use, it can be seen that every mile per day added to the productivity of this total by increasing efficiency, is the equivalent of 400,000 cars. Thus it is obvious that if a continuous movement of freight-cars to and from their terminal points can be obtained, a two-fold advantage will result; first, eliminating the delay and waste incidental to congestions, and second, releasing a vast number of cars for main-line traffic.

To say that this can be accomplished by utilizing the motor-truck is not a mere prophecy; it is a proved reality. The few railroads that have applied the use of trucks in their limited way to this problem have met with remarkable success and should stand as uncompromising examples to every railroad now affected by terminal congestion. For example, figures compiled by the U. S. Railroad Administration show that in the Big Four yards at Cincinnati, the use of motor-trucks with demountable bodies has reduced the time required per ton-mile for transfer shipments from 12 hours and 18 minutes, to less than 3 minutes. This saving of time is accompanied by a reduction of fifty cents per ton-mile on the cost of the transfer shipments. The motor-truck is now a permanent supplement to the railroads and has proved its capacity to take the short-haul traffic that has developed to be time-wasting and unprofitable business for them. By 'feeding' short-haul shipments to the main-line traffic, it has released thousands of cars for long-distance transportation and has done much toward relieving congestion at terminals.

CONVEYING HOT MATERIAL BY BELTS

An unusual problem in the handling of hot cement clinker with a temperature of 200° and over, was recently solved at the plant of the Standard Portland Cement Co. at Leeds, Alabama. The method decided upon for moving the clinker was a rubber conveyor-belt, but the clinker could not be cooled sufficiently in the process previous to conveying to prevent scorching of the belt and its rapid destruction. The answer to this problem was found by running the belt at an incline of 12°, so that the lower pulley dipped into a trough of water, thus carrying a film of cold water upon the belt, onto which the hot clinker from the loading hopper was deposited. At this point a new problem was met; namely, how to join the belt so that the belt's full strength would be retained, and in a way which would withstand the extremes of temperature, the wear on the pulleys and the abrasion of the clinker. For this purpose Crescent belt-fasteners were used, because they brought the belt ends tightly together in a snug joint, which made the belt practically endless on the pulley-side, so there was no opportunity for clinker-ash to get into the joint and abrade the belt-ends, and also because in this method of joining, no metal came in contact with the pulleys to cause wear. Moreover, exceptional strength of the heads of the Crescent rivets and the formation of Crescent plates prevented destruction of belt-joint through abrasion by the clinker.

In six months of operation, this conveyor has carried 61,000 tons of clinker, and the Standard Portland Cement Co. credits the saving of \$300 in belt-cost alone to this conveyor. The belt used was Goodyear 'hy-temp', which is made particularly to withstand temperatures up to 200°, and is adapted for work on conveying jobs in mines, coking-plants, and cement-factories where heat resistance and ability to withstand hard wear are prime requisites. Not alone on heavy drives, such as tube-mill, Griffin mill, crusher, and heavy conveyor units are Crescent belt-fasteners successfully used, but also on lighter drives of all kinds where dependability is an economic factor, as they assure continuous production. The Crescent Belt Fastener Co. has just published a new hand-book illustrating Crescent belt-fasteners in use on many different kinds of belting and under different conditions.

ASSOCIATION OF ACCOUNTANTS

The Industrial Cost Accountants Association was organized in Chicago on June 18 by representatives of leading manufacturers in various lines of industry. The object of the new association is the standardization of accounting and cost terminology and the adoption of standard governing principles; the promotion of active co-operation and interchange of experiences between representatives of manufacturers engaged in similar activities; the education of the members and their business associates in the complex economic problems of industry; to assist standardization committees in each line of industry in establishing uniform accounting and cost practices; to act as a clearing house in distributing to all members the development in cost practices to the end that uniformity, once established, may be maintained.

M. F. Simmons, of Schenectady, New York, supervisor of costs for all General Electric Co. interests, was elected president of the association. C. H. Smith, of Wilmerding, Pennsylvania, director of clerical operations of the Westinghouse Air Brake Co. interests, was elected first vice-president. Roland H. Zinn, of New York, was elected second vice-president. A. A. Alles, Jr., of Pittsburgh, secretary of the Fawcett Machine Co. and treasurer of the Schaffer Engineering & Equipment Co., was elected secretary-treasurer of the new organization. Headquarters of the association will be in Pittsburgh, at the office of the secretary-treasurer, 1501 Peoples Bank Building.

UNDERGROUND PROSPECTING AT JOPLIN

By F. R. Alger

For years there has been a need for some convenient and economical method of underground prospecting in the lead and zinc mines in the Joplin or Tri-State mining district; and this has been especially urgent in the Picher-Miami section recently developed. It frequently happens that the ore-body is worked out and the owners wish to locate, for operation from the same shaft, other bodies of ore on their prop-

Fig. 1. Sullivan Class FS-3 Rock-Drill

erty, without going to the expense of new openings from the surface. Often the presence of these bodies has been indicated by drilling from the surface. Sometimes their location is roughly determined by the geological indications. It is a well known fact that the 'runs' of ore frequently follow water courses, spreading out at some points and diminishing at others.

Sometimes the presence of these runs of ore is indicated above the mine stope; frequently they are below the general level of the mine. For this class of work, even in the high stopes of the Joplin district, the use of a churn-drill underground is impracticable. Although diamond-drilling has been demonstrated to be practicable the cost is high.

A method has recently been employed which gives promise of excellent success. This consists in the employment of a Sullivan 'Hy-Speed' rock-drill of large size, mounted on a tripod, and operated by compressed air. The machine employed is the Sullivan Class FS-3 machine, see Fig. 1, with 41-in. cylinders, mounted on a Lewis hole tripod, having a planed and slotted front bar, such as is used in quarries for drilling parallel holes to split granite blocks. The FS-3 machine is exceedingly substantial and powerful; it is equipped with a hollow piston and employs hollow drill-steel. With it, holes have been drilled in Joplin-Miami mines to a depth of more than 40 ft. and under favorable condition in this class of work the drill is capable of putting in 60-ft. holes. Round hollow steel of 1½ in. diameter is employed. For lengths above 15 ft. the steel is jointed, the joint itself being similar to that used in churn-drill practice. The different sections are connected by means of a double male

coupling, see Fig. 2, which fits the upset and threaded female ends of the drill-steel, and makes a substantial and readily handled coupling. A particular advantage of the

Fig. 2. Coupling for Drill Steel

FS-3 drill consists in the cushion valve at the front end of the cylinder. When running into pockets, or caves, damage to the front head may be prevented by throwing a lever near the front end of the drill, which puts a front head cushion into effect and relieves the drill entirely of the shock and danger of breakage from pounding on the front head. This feature is also of value in freeing steel that has become stuck.

This drill can put holes in any direction or at any angle. In the work already done, some holes were directed a little below horizontal, and others at an angle of about 60° above horizontal. The cuttings are preserved in the same manner as cuttings from a churn-drill hole, and provide a reasonably accurate record of the orebody penetrated. The advantages of this method of prospecting are obvious. In the first place the deep holes from the surface, running through 150 to 200 ft. of worthless cap rock, are avoided. In the second place, the angle at which the drilling is done permits the orebodies to be cross-cut, thus furnishing a valuable check on any previous vertical drilling. Third, a large saving in time is effected, as compared with other methods of prospecting.

AN IMPROVED STRETCHER

By J. C. Williams

A few years ago I made a litter or stretcher with a joint lengthwise through the centre through which ran a strap, which, when withdrawn, allowed the stretcher to separate like a door-hinge when the centre pin is withdrawn. At that time the care of injured employees took up but little time of the employer, who had not realized that a workman was an asset while he worked but became suddenly a liability when he was injured; the term 'first aid' was not yet coined. However, the largest industrial concerns suddenly woke up to the importance of caring for their employees, many States passed drastic laws to enforce care for injured employees and to guard against accidents. Today the large plant that has not a safety-engineer or first-aid superintendent is the exception and not the rule. We christened our stretcher from its inception 'Williams' Improved Stretcher', feeling sure that would include its past, present, and future, for it has been a succession of improvements—and the end is not yet. The only features remaining unchanged today are, the use of white duck owing to the fact that it can be washed when soiled, while colored ducks cannot be; and the size of the cot which remains, 2 by 6 ft., thus assuring interchangeability. Get a cot from us now and it will fit a stretcher bought of us two years ago. Practically all other stretchers are as alike as 'peas in a pod'—simply a strip of canvas, hem on each end, tacked to wooden handles with braces about one foot from each end for spreaders and iron legs riveted on, there are usually about seventy-five tacks to each side so it is out of the question to take the cot off to wash, in fact, this kind of stretcher is not intended to be washed, but to be thrown away when soiled and new stretchers bought. With our improved stretcher no two component parts are inseparable, for instance, the cot is in two interlocking parts, the rubber strap acting as lock, the spreader and legs are of one piece and easily slipped from the handles, the handles slip through a hem at each side of the stretcher, there are no tacks, no catches of any kind, so when it is taken apart, we have two handles, two spreading-iron and legs, one rubber

strap, and one each right and left-hand cots. Any and all of these parts can be perfectly cleaned. We sell our stretcher in a dust-proof bag so it reaches the customer clean and can be kept clean, always ready for instant use. Naturally we do not compete in price with the old-fashioned stretcher any more than mazda lamps do with kerosene lamps.

NEW AUTOMATIC CONTROL-PANEL FOR MOTOR-GENERATOR SETS

In mines and metallurgical plants where the direct-current supply is obtained from a motor-generator set, it is frequently advantageous to control the power equipment from some remote point, thus eliminating the necessity of an

or the breaker may be left closed and the equipment operated by means of the remote control-switch. The closing of the main circuit-breaker effects the closing of the phase-failure and reversal relay, unless one or more of the phases are open or reversed, in which case the abnormal condition must be moved from the line before the relay will close. This relay has also the characteristics of a voltage-relay, so the equipment will not operate if the line-voltage is very low. After the relay closes, the automatic starter connects the motor through an oil-switch to the low-voltage taps of an auto-transformer. When the equipment has come up to speed, the oil-switch opens and a second oil-switch connects the motor directly to the supply-line, at the same time completing a circuit to the closing-coil of the automatic re-

Switchboard for Automatic Control of Motor-Generator Sets

Rear View of Board, Showing A. C. Oil-Switches and Circuit-Breaker

attendant at the switchboard. Several mines are using with their motor-generator sets an automatic control-panel, shown in the illustrations, which has all the protective features used in the small modern switchboards, and may be controlled from any remote point by means of an ordinary snap switch.

This automatic equipment, manufactured by the Cutler-Hammer Mfg. Co. of Milwaukee, consists of the necessary circuit-breakers, switches, relays, fuses, and recording instruments mounted on slate panels carried on a floor-type frame. The primary equipment of the control-panel shown in the illustration consists of a hand-operated oil circuit-breaker provided with inverse time overload attachments, a phase-failure and phase-reversal relay, and an automatic starter of the auto-transformer type. This is to be used with induction motors, but the same general equipment with a few slight changes can be used with motors of the synchronous type. On the direct-current side a knife-switch, voltmeter, and ammeter with the necessary fuses, and an automatic re-closing circuit-breaker are provided.

With the remote control-switch 'on' the controller may be operated by merely closing the main-line oil circuit-breaker,

closing circuit-breaker, which immediately closes, establishing the generator voltage on the direct-current feeders. In case of an overload on the direct-current side, the circuit-breaker opens, and re-closes when the overload is removed. The oil-switches used on this equipment were described and illustrated in the January 10 issue of 'Mining and Scientific Press'. These control-panels can be furnished in different capacities up to 300 kw. and, when desired, can be built for operating two motor-generator sets in parallel.

The Worthington Pump & Machinery Corporation announces the purchase from the Platt Iron Works, Dayton, Ohio, of its drawings, patterns, jigs, templates, special tools, good-will, and name, in connection with the following products: (1) oil-mill machinery, suitable for the extraction of oil from all sorts of nut and seed products, comprising crushers, cookers, cake-formers, presses, filters, and pumps; (2) hydraulic turbine and water-wheels, including horizontal and vertical, high and low-head machines; (3) feed-water heaters, steel and cast-iron, horizontal and vertical; (4) high-pressure air-compressors for torpedo and other high-pressure charging, cleaning, and discharging.

SALES of copper during June were 52 million pounds, as compared with 62 in May and 101 in April, making a total of 215 million pounds for the second quarter of the year, as compared with 639 millions during the first quarter and 753 millions in the last quarter of 1919. Thus in nine months 1607 million pounds has been sold, besides 350 millions of copper refined in the other countries. The refinery output in the United States has been about 1250 million pounds during the nine months, indicating a reduction in world stocks of 357 million pounds. That is less than was hoped. At present the stock of refined metal in this country is about 400 million pounds, not counting the copper in course of treatment. The figures for the first quarter of this year show the effect of the crippled railroad traffic, which has been injurious both to production and consumption. It is apparent also that there has been a hitch in the arrangement for financing the export of copper to France. Moreover, our legal state of war continues to militate against our commerce in metals as in other commodities needed by Europe.

IN our last issue we mentioned the fact that the Mining Experiment Station of the U. S. Bureau of Mines has been moved from Golden, Colorado, to Reno, Nevada, because the trustees of the Colorado School of Mines declined to renew the contract whereby the Station was quartered in a suitable building, but offered new quarters in an unsuitable building, and stipulated that all work done by the Bureau in Colorado should be done at Golden. This last proviso seems to have been prompted by jealousy of the University of Colorado, at Boulder, where oil-shale investigations are being conducted by the Bureau. The trustees, it seems, have made a blunder. The editor of 'Chemical & Metallurgical Engineering', Mr. H. C. Parmelee, says: "The transparency of this subterfuge will be evident to those who are familiar with the location of the mill in the creek-bottom and its unfitness for use in the delicate and exact work conducted by the Bureau". This refers, of course, to the new site offered by the trustees. Mr. Parmelee knows whereof he speaks, for he was president of the Colorado School of Mines and had to resign, for reasons that do him no discredit. We are informed that the mining people of Colorado appreciate highly the work done by the Bureau of Mines at Golden and Boulder, and they "deeply deplore the action of the trustees". Meanwhile we note that the Lead and

Zinc Experiment Station of the Bureau of Mines is to be established at Rolla, and is to be conducted in association with the Missouri School of Mines at that place.

IN the current 'Atlantic Monthly' Dr. Frederick Starr, the anthropologist, describes Mexican politics for the benefit of the Boston *intelligentsia*. He finds many analogies between conditions upon the opposite banks of the Rio Grande; for example, Carranza's effort to force Ignacio Bonillas upon the Mexican people as his successor in the Presidency was like Roosevelt's successful effort in forcing Mr. Taft upon the American people. In both cases, says Dr. Starr, the result was the disruption of the party and war to the knife, but he overlooks the fact that the "war to the knife" in one case was figurative and in the other literal. He seems to think that fighting with ballots is much the same as fighting with bullets. Disregarding a difference that seems to us to be more than academic, he concludes that the American people is in no position to criticize the Mexican people. It is not the first time that an anthropologist has failed to understand the politics of his own day. We have more respect for the opinion of the small boy who was asked by his teacher: "Now, Johnny, can you tell me what is raised in Mexico?" The bright boy replied promptly: "Aw go on, I know what you want me to say, but ma told me to cut out that rough stuff."

AMONG the items of misinformation appearing on the editorial page of the 'Morning Howl' we note the statement that "Great Britain has found an effective mode of stimulating production in her South African mines in the shape of a disguised bounty to producers". The stimulation is due, of course, directly to the fall in exchange whereby more shillings have to be paid for an ounce of gold; the cause lies as much in New York as in London. The article in which the misleading assertion appears is meant to support the proposed \$10 excise-tax on manufactured gold under the terms of the McFadden bill. The chief objection made to this bill is that it is a piece of special legislation, in behalf of a relatively small industry. This, we must confess, is a valid objection, much as we may sympathize with the gold miner. Such legislation provokes log-rolling in Congress, after the fashion of the methods by which support is obtained for River and Harbor Bill appropriations and tariffs in favor of various domestic products. It has been suggested that a law be

passed forbidding the sale of gold by the Mint to manufacturers, but any such provision would be avoided by taking Federal Reserve notes and converting them into gold coin, which could then be melted into bullion. Another idea is to prohibit the use of gold in manufactures, thereby restricting its employment to monetary purposes. All such legislation is objectionable because it destroys the free market for gold, on which in the long run we must depend for a correction of the existing abnormal conditions. The problem is one that has world-wide implications; it is not local nor even national.

ON page 142 we give extracts from a speech made at Johannesburg by Mr. Samuel Evans, the chairman of the Crown Mines company. Mr. Evans is a man much respected for his sagacity and good sense. He stated that the premium on gold produced from January to May inclusive this year had averaged 21s. 1d. per ounce, which is equivalent to 25%. An ounce of gold is worth normally 84.95 shillings. The premium, he said, represented 7s. less than the increase in cost per ounce since 1913, which therefore must have been 28s., or \$6.75, per ounce produced. White wages have increased 69% since 1915; the average earnings of European workers have risen 64.6%; stores cost 33% more, and other costs are 36% higher than five years ago. The purchasing power of gold in South Africa, however, has not fallen as rapidly as in England, where it is half what it was in 1914. If the commodity price of gold had remained as it was in 1896 the average cost of mining on the Rand would be, according to Mr. Evans, under 12s. per ton as against the actual average of 22½s. last year and the higher figure this year. The banks of South Africa have been issuing paper money at an accelerating rate and they seem bent upon "plunging the country deeper into the paper-money bog". In this respect South Africa is no solitary sinner. The gold held by the 31 principal countries of the world is only two billion dollars more than before the War, whereas the pile of paper money is larger by 43½ billions.

WE can think of no act of courage more unselfish or more splendid than to enter a burning or caving mine in an effort to save the life of fellow workmen. The risk is not faced on the spur of the moment, it is taken knowingly and deliberately; it means entering a dark hole in the ground where the story of a valiant effort may be buried with the bodies of those in danger and their would-be rescuers, and even if successful there can be nothing of the spectacular in the performance; there is no glamor of heroic achievement before an admiring crowd; often there is less chance of saving the lives of the imperiled ones than of losing those of the men that seek to aid them. It is an everlasting tribute to the miner that invariably when the emergency arises someone quietly undertakes the task of rescue. On the occasion of the international first-aid and mine-rescue contest to be held at Denver next September Dr. Frederick G. Cottrell, Director of the U. S. Bureau of Mines, on behalf of the Joseph A. Holmes Safety Association, will

present gold medals and appropriate diplomas to four miners, and to the nearest surviving relatives of three others, who lost their lives in their effort to succor fellow-workmen. Mr. John L. Boardman, wearing an oxygen helmet, single-handed saved three men who had been overcome by gas from a fire in the West Colusa mine at Butte. Mr. Daniel Bionvitch jeopardized his own life by running his electric locomotive three times into the fire-zone at the Balkan mine in Bewalik, Minnesota, on each trip bringing out men whose lives were imperiled. At the Gold Hunter mine, near Mullan, Idaho, two miners were entombed as a result of a fall of ground. Mr. James Collins and Mr. James Dillmark, while endeavoring to help their comrades, were themselves caught by caving rock. They were later rescued although buried to the shoulders in broken ore. Messrs. Michael Conroy, Peter Sheridan, and James D. Moore particularly distinguished themselves in the terrible fire in the Speculator mine at Butte, in which they and 168 other miners lost their lives. The heroism of these three, however, stood out particularly, and their relatives are now to receive the honors that the men so unselfishly earned. The other men named will receive their medals in person. There are doubtless others both living and dead who under similar circumstances have performed deeds equally worthy. To them, let us hope, has come reward no less than to these whose heroism is to have a public recognition so richly deserved.

Metal Quotations

Great is truth and it will prevail, says a Latin proverb. We are amused to read the naive and belated confession of the 'Engineering and Mining Journal', in an editorial appearing in the issue of July 10, acknowledging that its metal quotations are merely approximations, of a character unsatisfactory even to its editor. For many years we have insisted upon the absurdity of mine-operators selling their ore and basing their wage-scale on the guess of a trade-paper in New York. Heretofore our contemporary has insisted upon the essential accuracy of its weekly guesses and it has suited the metal-buyers to accept its figures in the settlement of purchases from the smaller mining companies. The big ones, of course, avoided doing anything so foolish; they sold their metal through their own agencies. We have insisted again and again that the price at which copper, for example, is sold by a given individual or company may be ascertained definitely, but the average price at which a variable number of producers at varying intervals sell varying quantities of copper cannot be determined by anybody, unless all the transactions are known accurately, that is, a true weighted average has never been available to the trade. Only recently the editor of the 'Journal', anxious to prove that the papers of the McGraw-Hill agglomeration were not "in collusion" as to metal prices, showed what discrepant quotations they have been giving their readers. Of course, he proved too much; we hastened to excuse the 'Journal' from the charge of collusion and we absolved it also of the imputation of accuracy. So now

the editor rounds the incident by confessing his quotations to be "unsatisfactory" because they are mere "approximations" of the truth. He deserves credit for his frankness; in future there can be no misunderstanding as to the real character of the 'Journal's' metal prices. There will be no excuse for relying upon them; there never was. Sellers of ore can, and should, settle on the price that the smelter obtains for the metal in their ore; miners can, and should, base their sliding scale of wages upon the price that the company obtains for its metal for the month; as the metal is sold in advance, there need be no trouble in adopting such an arrangement. It is a clear gain to the industry that a fake should have been acknowledged at last.

Smelting Lead-Zinc Ores

Last week we published a paper by Mr. Gilbert Rigg in which he detailed recent improvements in the practice of roasting and smelting lead-zinc ore from Broken Hill at the Port Pirie plant. A number of well known metallurgists associated with smelting enterprises in other countries joined in the discussion of the paper and their remarks, together with an informal reply by Mr. Rigg, appear in the June bulletin of the Institution of Mining and Metallurgy. Mr. Rigg has recently completed a tour of the United States in the course of which he visited a number of the big smelters, and his comments are doubtless enriched by his observations in this country. The discussion therefore brought together ideas on modern practice in lead smelting from many parts of the world. Mr. S. J. Speak described briefly the blast-furnace smelting of an oxidized lead-zinc ore in northern Rhodesia. The furnaces were run in a decidedly unusual way. The charge-column had a height of only 12 feet above the tuyeres, the blast-pressure was maintained at less than 8 ounces, and the slag, which averaged 20.5% zinc oxide, contained 43% ferrous oxide and was extremely low in lime, the average analysis for lime and magnesia combined being only 2 to 3%. The capacity of the furnace was but two tons per square foot of tuyere-area, and the slag usually contained 7% lead. Obviously this remarkably high lead content suggests faulty reduction and the question arises why a higher charge-column and a correspondingly increased blast-pressure could not be used. Moreover, the necessity for a moderate proportion of lime to obtain good reduction is generally recognized. A query from Mr. Rigg, as to whether any attempt had been made to determine the particular form of the lead in the slag, was answered in the negative. Without intending any reflection on those in charge of the plant in Rhodesia, there appears to be a fruitful field for painstaking and systematic experimental work with an excellent chance for revising the practice in such a way as to effect a decided decrease in the amount of lead in the slag; but final criticism would be imprudent, as the economic conditions may have been such as to warrant the procedure described. While on the face of it the metallurgy appears to be bad, it is certainly no more repre-

hensible than, for instance, the practice formerly in vogue at Port Pirie of feeding old slag, in proportion ranging from one to two times the remainder of the charge, as a sort of physic to flush the zinky matte through the blast-furnace. The cost of quarrying this slag, the additional fuel required, the reduction in effective capacity of the furnaces, and the cost of the final disposal of the extra slag from the furnaces were obvious defects, and, as was later demonstrated, they were all unnecessary. The consensus of opinion was that a high zinc content in the sintered material causes trouble in the blast-furnace only when the roast has not been effectual in reducing the total sulphur to a point considerably below what would be allowable were the zinc not prominent; in fact, the prime essential for the smooth operation of the furnaces, when the analysis shows more than 15 or 16% of zinc oxide, is the removal of the sulphur. At Port Pirie the sulphur in the sinter is kept at approximately 2.5%. In this connection Mr. J. C. Moulden pointed out that at Cockle Creek difficulty has always ensued if the silica content of the slag, containing 20 to 22% of zinc oxide, is allowed to rise above 20%. Mr. H. C. Lancaster injected a novel suggestion. He had noted that, whereas slags containing 15 or 16% of zinc oxide were generally conducive to trouble, slags running 30 and 32%, in his experience, had been quite fluid and exceptionally low in lead. He inferred that there might be a critical point in the neighborhood of 20% beyond which the difficulties incident to the presence of zinc diminished. Mr. C. O. Bannister was impressed with the possibilities opened up for an alternative method of beneficiating a lead-zinc ore. The trend of metallurgical development has been in the direction of making two exceptionally clean concentrates, one of lead and the other of zinc; this result, of course, being facilitated by the use of flotation and fine grinding; if, however, as seems probable, a lead concentrate containing a reasonable proportion of zinc can be smelted successfully and economically and the zinc afterward recovered from the slag, the older and more simple methods of concentration might be revived. Several schemes for de-zinking slag are available. At South Chicago two methods have been tried, namely, charging the slag in lumps, and feeding briquettes made of ground slag and pulverized fuel. The use of briquettes gives a higher extraction, but, of course, introduces a considerable extra expense. Blast-furnaces for de-zinking have been used in the United States and Germany, but the best success has been obtained in reverberatories, fed at the side. This last point is important because of the fact that the zinc-oxide fume is driven off before actual fusion occurs; accordingly the fuel-ratio and the operation must be regulated to avoid actual melting, or the recovery will be poor. Reverting to the roasting process, Mr. W. Dewar agreed with Mr. Rigg that the three principal considerations in any roasting operation are temperature, time, and ventilation or contact of the ore particles with the air; and that the three are complementary factors. In blast-roasting the third factor is emphasized and the time is consequently reduced. He

points out that the difficulty is to keep the charge from becoming hot enough to fuse before roasting is complete, and that this may be accomplished by the addition of limestone, iron oxide, and slag, and by damping the ore preliminary to the roasting process. Primarily, blast-roasting has the tremendous advantage of large capacity. Mr. Riggs' figures indicate that in 24 hours 270 pounds of sulphur is driven off per square foot of hearth-area as against only 5 pounds in a furnace of the superimposed-hearth type. However, the efficient utilization of Dwight & Lloyd machines or Huntington & Heberlein pots depends upon a careful study of the physical, no less than the chemical, characteristics of the material to be smelted. There seems to be a tendency, when a process has been developed to a point where good results are obtained, to subside to a rule-of-thumb practice. Perhaps also, metallurgists, like the rest of us, are prone to take up fads and to centre on them their entire attention while the more familiar methods suffer from neglect. Without advocating by any means a policy of metallurgical Bourbonism we venture to say that much may be gained by devoting more time, talent, and energy to scientific research in some of our supposedly perfected processes.

The Federal Trade Commission

We have received a copy of a speech delivered by Mr. William B. Colver, a member of the Federal Trade Commission, at Atlantic City on July 8. We note that he says that "the Commission has been created to aid in keeping the channel of the River of Commerce free from obstructions and the Ships of Commerce moving freely without undue interference, one with the other". He says that the spirit of the legislation under which the Commission was created is expressed by the phrase: "Unfair methods of competition in commerce are hereby declared unlawful," and he proceeds to expatiate on this text by saying: "This declaration means that in commerce there shall not be trickery or chicanery; that there shall not be the rule of might as opposed to right; that unfairness, meanness, ruthlessness, and dishonesty have no place in American business." Which reminds us of Mr. Bryan's proposal to compel equality of punishment between the sexes in regard to infractions of the seventh commandment. However, if the Federal Trade Commission can help toward the much desired consummation of promoting clean and fair business methods all the way from New York to San Francisco, or from Cape Cod to Cape Nome, it will deserve, and obtain, the gratitude of all good citizens. We take an interest in Mr. Colver's remarks because we were present at, and even participated in, a recent hearing before the Federal Trade Commission in San Francisco when its representatives were taking evidence in the matter of the complaint against the Minerals Separation people. This slight experience of its methods and the reading of the voluminous record in this particularly interesting case prompt the remark that the procedure, like that of the courts in patent cases, seems curiously ill adapted to eliciting

the truth. In the first place, counsel for Minerals Separation understands the affairs of his company thoroughly; he has himself testified that he is a director of the Minerals Separation North American Corporation, and a stockholder in that corporation, "or rather, a holder of voting-trust certificates". He holds the whip-hand over counsel on the other side, who do not understand the flotation controversy nearly as well, and are bent apparently on a general fishing expedition in the course of which they expect to catch some high-smelling game. The method is something like the old equity procedure termed a 'bill of discovery'. The respondents have had to submit to a search among their papers and an investigation of their correspondence such as must have proved extremely irritating. We would not spare that irritation, remembering the high-handed and inquisitorial methods that they themselves have adopted toward the operators of mines and mills, but we can readily see that the methods permitted under the law to the Federal Trade Commission are open to grave abuse. As the identity of the complainant and the period covered by the actions of which complaint is made are not disclosed to the respondents or to the public, it is impossible to appreciate how much or how little of the testimony is pertinent. One thing is sure, there will be an enormous mass of it to be digested by the members of the Commission before they can deliver a decision. The proceedings were started a year ago and the hearings began on April 7 last in New York. They are now being held in San Francisco, Salt Lake City, and Denver. Months must elapse before they are finished and more months before the record is corrected and revised for presentation to the Commission itself. A great deal of irrelevant matter has been put into the record, simply because it is impossible for the presiding officer, the Commissioner, to tell off-hand how much of it has a bearing on the issue. Opposing counsel engage in long and wordy debates, not to mention acrimonious squabbles, over points that seem quite immaterial. The proceedings in San Francisco, under the direction of Mr. Huston Thompson, seem to have been more orderly than they were in New York, so far as we can judge by the record, but even the Commissioner who presided here had to allow a wide latitude in regard to the discussions initiated by counsel on both sides. This does not impress the spectator as an efficient method of inquiry. It is, of course, an old-fashioned way of getting at the truth, but it is woefully clumsy. In so far as the inquiry runs parallel with the case now before the Court of Appeals at Philadelphia, it is regrettable, for the hearings before the Commission are quite unsuited to the ventilation of technical questions, apart from the unseemliness of traversing issues that are being tried elsewhere. The inquiry will, we expect, elicit ample evidence of the queer practices of the Minerals Separation people and we hope that it may lead to their being disciplined for any infraction of the Clayton act, if they have been guilty thereof, but it will, we fear, fail in loosening the blighting tentacles of that patent-exploiting agency.

DISCUSSION

The Price of Gold

The Editor:

Sir—In your issue of June 26, Mr. A. Moline says that the conclusions in my letter appearing in your issue of March 6 are based on a misconception. He states that, "when gold was quoted in London at £6 per ounce it meant that for an ounce of gold you could get six British notes or a negotiable instrument of equal face value, or the equivalent value in other goods, but six sovereigns could not be got for an ounce of gold under any conceivable conditions." He then goes on to show that if one could get six sovereigns for an ounce of gold they would be immediately melted down, making an ounce and a half of gold, for which one would proceed to obtain nine sovereigns, and so on *ad lib*.

The weak points in Mr. Moline's argument are:

1. That in Great Britain it is illegal to mutilate or destroy sovereigns. When the price of gold rose in England during the War, the immediate effect was the violation of the law, by certain of the public, in melting down sovereigns. The British government at once took steps to prevent this.

2. A British note, or a negotiable instrument of equal face-value, is a promise to pay gold, in the ultimate. It is quite conceivable that if a person must have gold for an industrial purpose, he should give a promise to pay six sovereigns for an ounce of gold at some future time, and this was actually the case.

In support of what I have said, I would recommend Mr. Moline and others to read and re-read the masterly address delivered by Mr. Francis A. Govett at the annual meeting of the Ivanhoe Gold Corporation, part of which was published in your issue of June 5. If you will allow me I shall quote Mr. Govett as follows: "For six years past, except nominally, the convertibility has been suspended, and, except in very small amounts, you could not get gold for notes; but the credit of the note—the currency, either Bradbury or Bank of England—has not been damaged to the extent of a penny piece. The fact that prices have risen does not mean depreciation of the currency; nor is currency inflated; currency is not inflated until the currency in circulation is in excess of the demand. At the present time more people with higher wages have been competing for scarcer commodities, more currency has been required, and paper internally has not depreciated in gold. Try it for yourselves. You can get probably 50 or 100 sovereigns from the bank, once at any rate, without being followed by a detective; go and see if you can buy more commodities with your hundred golden

sovereigns than you can with a hundred Bradburys. You cannot do it unless you sell your gold to an illicit buyer who proposes to melt it down."

In view of this I regret that I cannot accept most of the five basic facts laid down by Mr. Moline. If No. 5 is correct, that "bar gold of specific fineness and sovereigns or other gold coin are interchangeable on a fixed arithmetic basis only", then why should an illicit buyer of sovereigns want to melt them down? No. 4, which states, "The price is expressed in the unit of measurement in current use, and just now that is paper currency, not metallic currency," is sufficiently well answered by the quotation from Mr. Govett.

THOS. FRENCH

Guelph, Ontario, July 8.

[Mr. French is, we think, inconsistent. He takes issue with Mr. Moline when he says that "six sovereigns could not be got for an ounce of gold under any conceivable conditions" and then immediately quotes Mr. Govett as saying "For six years past, except nominally, the convertibility [of notes] has been suspended. . . ." Messrs. Moline and Govett in substance concur, although Mr. French apparently does not think so.—EDITOR.]

An Interesting Experiment

The Editor:

Sir—The results of the experiment described in the communication from Charles W. Gardner, which appeared in your issue of June 26, are "remarkable and unexpected" if the conditions of the experiment were exactly as described, namely that the outer end of the gold strip was above the level of the quicksilver in the vial. By substituting a lamp-wick for the strip of gold and water or oil for the quicksilver the forces involved remain the same. When the outer end of the wick is below the level of the liquid in the vial, the liquid will drip from the outer end of the wick; in other words, the wick will act like a siphon. Quicksilver wets gold just as oil wets a lamp-wick, and the so-called capillary attraction causes it to climb up. When it reaches the top and spreads over to the downward-hanging segment gravity helps to pull it down, so it accumulates at the lower end and finally drops off, drop by drop.

The statement that in 30 days 1.9 grains of gold had been "dissolved" by the quicksilver needs further explanation. It cannot be literally true, for the solubility of gold in mercury is very low, certainly not over 0.1% at ordinary room temperatures. The exact quantity of quicksilver used is not given but was apparently about 500 grains, which would suffice to dissolve only half a

grain of gold. Gold dissolves mercury, however, forming one or more intermetallic compounds, as I have described in some detail in Vol. XXXVII of the Trans. A. I. M. E. This appears in the form of distinct crystals, first described by A. H. Chester in 1878, which seem to become detached and float about in the quicksilver. It is apparently for some such reason as this that the published data as to the solubility of gold in quicksilver vary quite widely, for Dudley found that the apparently dissolved gold could be partly removed by filtering the quicksilver, and my own results confirmed this. Our results indicated that the solubility of gold in quicksilver at 20°C. is not over 0.06%, and may be much less, the figure given representing our limitations as to filtering media, rather than the actual solubility.

THOMAS T. READ.

Washington, July 6.

The Editor:

Sir—The experiment described by Mr. Chas. W. Gardner in your issue of June 26 may be explained as follows:

The affinity of gold for mercury caused the gold bar to act like a wick, up to the point of saturation. Upon saturation, gravity caused the mercury to accumulate on the lower outer end of the bar and drops to form. When the first drop began to form the forces acting were gravity, amalgamation, resistance of the gold to passage of mercury, and the surface-tension of mercury: that in the vial tending to force mercury up the bar and that enveloping the drop tending to force mercury back along the bar toward the vial. The resultant coincided with that of gravity.

In the second experiment, conducted under water, there was a hydrostatic head in the vial and on the outer end of the bar, which exactly balance. In the vial its sides were wetted by water but the convex surface of the mercury was not wetted. Consequently the surface-tension of the water in contact with the mercury caused a downward pressure, which the mercury transmitted along the bar. On the outer end of the bar and acting against the tendency toward the growth of a drop, there was likewise an unwetted mercury surface enveloped in a skin of water, the tension in which, per unit of surface, was greater than the surface-tension on the mercury in the vial, but acting in the opposite direction. This minute unbalanced force acting opposite to the resultant of all the forces in the first experiment sufficed to prevent the discharge of mercury from the vial in the second experiment.

If it be argued that this force is insufficient to suppress the formation of the mercury drop, one need but consider that 168 hours were required to form the first complete drop; which proves that the resultant of the unbalanced forces in the first experiment, as measured by its effect, was exceedingly minute; therefore a like minute force acting in the opposite direction would restore equilibrium. In the second experiment this is exactly what happened.

Proof of this explanation can be had if a third experi-

ment, performed in water, to which is added a liquid to sufficiently diminish its surface-tension, as for instance alcohol, yields results as in air.

MARTIN SCHWERIN.

Cave-in-Rock, Illinois, July 6.

Stiff Hats for Miners

The use of helmets during the War has accentuated interest in the use of stiff hats in mines to protect the miners against falling rock. About 40% of the accidents in mines result from this cause. A large number of these accidents could be prevented if the miners wore stiff hats or helmets. The use of protective devices for the head in mines is not new, for they have been in use for many years in Europe and in the Lake Superior district in the United States. In practically all of the mining districts in Europe stiff hats of some kind are required by the managers of the mines. George S. Rice, chief mining engineer of the Bureau of Mines, reports that in Germany, Belgium, and France stiff hats made of papier mache or felt rosin are in use. Similar hats are generally employed in the Lake Superior district. In building the subways of New York and Philadelphia it was the practice of engineers and workers to let the hair grow long and to wear a close fitting cap or felt hat. In Germany the hats are high, like the military helmets, whereas in France and Belgium they fit more closely to the crown. In England both kinds are worn. As a rule the miners use soft padded caps, but in Yorkshire many of the miners use tight-fitting caps of sole-leather made on a jockey pattern with the seam forming a little ridge down the middle of the cap. These hats are useful in low thin beds of coal, as in crawling one is likely to strike his head on a sharp piece of rock or on a timber. It must be admitted such hats do not stick on well, though this is usually due to their not being specially fitted. The German hat is unsuited to an American-shaped head.

It is interesting to note that on the Continent tight cotton caps are generally worn over the hair and under the hard hat. This is a measure for cleanliness. In low beds of coal where much crawling on hands and knees is necessary the dirt and coal dust sift down, making the miner black and dirty. In metal mines stiff hats are of especial use in shaft-work; also in raises or high stopes. A small fragment of rock falling some distance either down a shaft or raise would kill a man if it struck him squarely on the head. A stiff hat or helmet may protect him and save his life. At a station in a shaft where men are loading a cage or skip, some kind of adequate head protector should be compulsory. A head-protecting cap which is also a good insulator should be worn where there is danger of striking one's head against a wire carrying an electric current. As a rule, miners are more willing to take chances than to wear a hat that is cumbersome or hot. The European miners have become so accustomed to the use of a head-protecting device that wearing one has become second nature to them. It would be desirable if stiff hats were in more general use in our mines.

Problems in Mine Ventilation

By WALTER S. WEEKS

We have completed our discussion of the method of determining mine-resistance. When the mine-resistance has been calculated, a fan can be specified that will be suited to the work.

Another phase of the problem of ventilation is to predict the amount of air that a given fan will circulate if the resistance is known. This type of problem occurs in tunnel-driving where the air is forced to the breast through an ever increasing length of pipe. We should like to know how much air the fan will deliver at different periods during the advance of the tunnel.

Through the kind permission of the American Blower Co. I am able to use its chart showing the drop in pressure in air-pipe. See Fig. 1.

Let us assume that a tunnel is to be ventilated with a 16-in. pipe. The tunnel is to be driven 4000 ft. The static-pressure characteristic of the fan when operated at the rated speed is shown in Fig. 2, curve *A*. How much air will this fan deliver when the tunnel is in 2000 ft. and how much when it is in 4000 ft? From the pipe-chart we read the drop in pressure in a 16-in. pipe per 100 ft. with amounts of air from 0 to 6000 cu. ft. per minute in circulation. The drop in pressure for other lengths may be easily calculated, as it is proportional to the length. The resistance offered by the tunnel to the returning air after it leaves the pipe is generally negligible because of the low velocity.

We may plot on the chart with the fan characteristic the pipe characteristic that shows the drop in pressure in a given length with varying amounts of air. In Fig. 2, *B* is the pipe characteristic for 2000 ft. and *C*, for 4000 ft. The point where a pipe characteristic and a fan characteristic intersect shows the pressure and quantity at which the system reaches equilibrium. The quantity that will be delivered may be read vertically below the point of intersection. The same method might be used to determine how much air a large fan would circulate in a mine but the computation would be tedious.

EFFECT OF VARIATION IN SPEED. It is often desirable to have the pressure-volume characteristics of a fan for several different speeds. If the characteristic at one speed is available others may be computed.

In Fig. 3, *A* is the characteristic of a fan running at 1000 r.p.m. Let us determine the characteristic at 2000 r.p.m. We know that if we double the speed we double the air and obtain four times the pressure if the conditions are unchanged. Select any point on the curve *A* and we obtain the combination of pressure and volume which occurs when the orifice is open a certain amount. If we were running a test at double the speed, at some time we should have this same gate-opening. When that happened the fan would deliver twice the air, at four

times the pressure, that it did at 1000 r.p.m. So if we select any point on the 1000-r.p.m. characteristic and multiply the quantity by two and the pressure by four we shall obtain a point on the 2000-r.p.m. characteristic. Curve *B* is the 2000-r.p.m. characteristic constructed from curve *A*. The density of the air is assumed to be the same in both cases. By plotting a number of curves at different speeds on the same sheet as used for the pipe characteristics, a complete knowledge of a tunnel-ventilating system may be gained.

OPERATION OF FANS IN SERIES. When the limiting speed of a fan is reached and the pressure produced is inadequate, the pressure may be increased by connecting fans in series; that is, the discharge of one fan is piped into the suction of another. Any number of fans may be operated in series. The same result may be obtained by placing the fans at intervals along the line. If the fans are close together a high pressure is produced at the entrance of the pipe. Accordingly if the pipe-line is full of leaks much air will be lost.

Fig. 4, *A* and Fig. 5 are the characteristics of two fans that are to be operated in series. To determine the result of such a scheme we plot a combined characteristic curve by adding the water-gauge readings produced by the two fans with the same given quantity. Curve *B*, Fig. 4, is the combined characteristic. Whichever fan is receiving air from the other produces a slightly higher water-gauge than when running alone because it does not have to accelerate the air at the inlet, and because it is handling air of a higher density, but consideration of the extremely slight difference is unnecessary.

The smaller fan will be a help where the quantity is less than 30,000 cu. ft. per minute. At that point it is circulating its maximum amount of air and the static pressure produced is zero. If more air than this is circulated the smaller fan will be a hindrance because a part of the pressure produced by the larger fan will be consumed in forcing the air through the smaller, and so the two in series would deliver less air than the larger one alone. The combined characteristic curve may be treated as the curve of a single fan.

THE OPERATIONS OF FANS IN PARALLEL. The study of the operation of fans in parallel is somewhat more complicated. Let us assume for the purpose of exposition that conditions are as shown in Fig. 6. Fan No. 1 blows air through 300 ft. of 12-in. pipe to the point where 200 ft. of 12-in. pipe brings the air from fan No. 2. The ducts unite at *B* and the air is then conducted through 500 ft. of 18-in. pipe. In Fig. 7, curve *A* is the characteristic of fan No. 1 and in Fig. 8, curve *C* is the characteristic of fan No. 2. The problem is to determine the load that each fan will assume. First plot the pipe characteristic

FIG. 1. CHART SHOWING DROP IN PRESSURE IN PIPES

of the 18-in. pipe on either chart. It is shown in Fig. 8, curve *E*.

Next on the chart for fan No. 1 plot the characteristic of its pipe up to the junction. Curve *B* in Fig. 7 is this

curve. Then on the chart of No. 2 fan plot its pipe characteristic. This is *D* in Fig. 8. The pressure at *B* (Fig. 6) will be determined by the total quantity of air that flows through the 18-in. pipe. The air that flows from

either fan must contain, when it reaches *B*, a pressure equal to the pressure at *B* so the amount of static pressure that can be consumed in the pipe from either fan before reaching *B* will be the static pressure produced by the fan when the air is flowing, minus the pressure at *B*.

Assume the total amount of air and 'pick-off' with a pair of dividers the pressure at *B* from curve *E*, Fig. 8.

FIG. 2

Place one point of the dividers on curve *C* with the other point vertically beneath. Keep the first point on the fan characteristic and move the dividers along until the other touches curve *D*. Read the amount of air that the fan will then give. This amount subtracted from the total amount assumed must be what the other fan will deliver.

Turning now to Fig. 7, without altering the dividers, place one point on the intersection of curve *A* and the

FIG. 3

quantity line just computed for fan No. 1. If, when the other point is vertically beneath the first, it does not fall on curve *B* our first assumption of the total air was incorrect and we must make another and repeat the operation. If the point does fall on curve *B* the assumption was correct and the division of the air will be as computed.

EXAMPLE. Assume 4050 cu. ft. per minute as the total

air. To drive this through the 18-in. pipe the pressure at *B* must be 2.6 in. We have then available for the pipe from No. 2 fan the water-gauge that it will produce minus 2.6 in. When 1750 cu. ft. is flowing from fan No. 2 the drop in pressure in the 12-in. pipe is 1.5 in. With this amount of air the fan produces a water-gauge of 4.1 in. so there will be left 2.6 in. at *B*. The difference between 4050 and 1750 is 2300, or the amount that the other fan will deliver. When 2300 cu. ft. is flowing from fan No. 1 the drop in the 12-in. pipe from fan No. 1 is 3.9 in. The

FIG. 4

fan produces 6.5 in. with this quantity, so the air when it reaches *B* will have the 2.6 in. of static pressure that is required. Of course it took several assumptions to solve this example.

THE ECONOMIC SIZE OF AIRWAYS. The cost of driving air through a duct depends to a large extent upon the resistance offered by the duct. In selecting the best cross-section for an airway, the one having the smallest ratio of perimeter to area should be selected if possible. The reason for this may be seen by inspecting the formula for friction. Obviously the duct should be made as smooth as feasible. After the shape of the duct is decided upon, it becomes necessary to fix upon the size. In this matter the cost of transmitting the air is the arbiter. The

FIG. 5

question may be best discussed by using a concrete case.

Let us assume that we are to sink a circular air-shaft 1000 ft. to connect with the mine-workings. The shaft is to be in use for twelve years. It costs \$20 per cubic yard of excavation and 100,000 cu. ft. of air per minute is to pass through the shaft. The efficiency of the fan and motor is 60%. The coefficient for friction is assumed to be 0.000,000,007,3. Power costs \$150 per horse-power-

Table No. 2. Data on Fans

No.	Outlet velocity	Speed r.p.m.	Mechanical efficiency	Horse- power	Price
1	4200	352	67.0	120	\$1424
2	3500	308	65.5	115	1712
3	3000	276	64.5	111	2024
4	2580	254	60.0	116	2432

Table No. 3. Yearly Charges Against Fans

No.	Capital	Power	Total
1	\$421	\$19,950	\$20,371
2	456	19,200	19,656
3	495	18,450	18,945
4	545	19,350	19,895

year. What should be the size of the shaft to transmit the air most economically?

Let us consider yearly charges. There will be two types of charges, namely, capital and operating. In the capital charge there will be interest and amortization. The money invested in the shaft will carry, let us say, an interest rate of 6%. Assuming that safe bank interest is 5%, an amount must be charged against the shaft each year, which, if placed in the bank at the end of each year, at compound interest, will at the end of twelve years equal the cost of the shaft. The only operating charge that varies with the size of the shaft is that for power so this alone must be considered in this group. We must now take a series of diameters and determine the yearly capital charge and the yearly operating charge.

The sum of these will constitute the total yearly charge for transmitting the air. If we plot curves with the various shaft-diameters as abscissae we can determine which diameter will be the cheapest. To illustrate the method of making the calculation I shall give the computation for an 8-ft. shaft.

An 8-ft. shaft 1000 ft. deep will have a volume of 1861 cu. yd. Its cost at \$20 per cubic yard will be \$37,220. The yearly interest charge at 6% will be \$2233. To figure the amortization we must have a sinking-fund table. Table No. 1 gives the amount which will accumulate in any number of years, if one dollar is placed in the bank at the end of each year with interest compounded annually.

One dollar put aside each year at 5% will according to the table amount to \$15.91. In order to have \$37,220 at the end of twelve years we must put aside at the end of

$$\frac{37,220}{15.91} = \$2339$$

The total yearly capital charge will be
\$2233 + \$2339 = \$4572

The amortization charge will be the cost of the shaft multiplied by $\frac{1}{15.91}$ or 6.29%.

The total yearly capital charge then will be 12.29% of the cost of the shaft.

The drop in pressure in the shaft computed with the friction formula is 2.78 in. of water or 14.46 lb. per sq. ft. The horse-power, assuming a 60% fan efficiency, is

$$\frac{14.46 \times 100,000}{0.6 \times 33,000} = 73$$

At \$150 per year 73 hp. will cost \$10,950.

The total cost for transmitting the air will be
\$4572 + \$10,950 = \$15,522

Such a calculation must be made for a sufficient number of diameters to determine which will be the most economical. The results for this particular problem are plotted in Fig. 9. The curve for total yearly cost is lowest with a 10-ft. shaft. So this will be selected. It will cost \$10,744 per year to transmit the air through the shaft. If an 8-ft. shaft were selected by guess it would cost \$15,522 per year and the owners during the twelve years that the shaft is to be used would lose, unnecessarily, about \$57,000. This method of determining the cheapest airway should be applied to the pipes in tunnel ventilation as well as to mine-openings.

THE ECONOMIC SIZE OF FAN. I shall discuss the selection of a fan by means of an example. The shaft which we have selected connects with a mine. We have apportioned the 100,000 cu. ft. to the mine-workings and we have calculated the mine-resistance exclusive of the air-shaft and found it to be 1.22 in. The resistance of the shaft is 2.78 in., so the total mine-resistance is 4 in., and when 100,000 cu. ft. is flowing through the mine a water-gauge at the collar of the shaft would read 4 in. The area of a 10-ft. circular shaft is 78.5 sq. ft., so the velocity of the air in the shaft will be 1275 ft. per minute. We decide upon the type and make of the fan and then ask the manufacturer to submit a list of different sizes which will give 100,000 cu. ft. of air per minute at a

static pressure of 4 in., and at an outlet velocity greater than 1275 ft. per minute. The list that we receive is shown in Table No. 2. The size of the fan increases with the manufacturer's number. We are told that No. 1 fan is operating at the high point on the efficiency curve. Any one of these fans operating at the speed stated will deliver the prescribed amount of air at the designated pressure.

Let us first see how this table illustrates some of the

FIG. 6

principles that we have learned. No. 1 fan is operating at the peak of the efficiency curve, hence the ratio of static to velocity that is shown here will indicate to us the ratio at which this type of fan is most efficient. The outlet velocity is 4200 ft. per minute, so the velocity-pressure is $\left(\frac{4200}{4000}\right)^2 \times 1$ or 1.1 in. of water. The ratio of static to velocity is $\frac{4}{1.1}$ or 3.64. The larger fans, since they have larger discharge-openings, will have a smaller outlet-velocity with 100,000 cu. ft. of air. Since the static pressure in all cases is 4 in., the ratio of static to velocity in-

FIG. 7

creases with the size of the fan and so we should assume that the mechanical efficiency would decrease. The table shows this to be the case.

The table states that the No. 1 fan requires 120 hp. This should be checked. The velocity-pressure is 1.1 in. and the static pressure is 4 in., so the total pressure is 5.1 inches.

$$Hp. = \frac{5.1 \times 5.2 \times 100,000}{33,000 \times 0.67} = 120$$

The ratio $\frac{5.2}{33,000}$ always appears in this type of calculation.

The quotient is 6350. A person used to working such problems would at once express this equation for slide-rule computation thus:

$$Hp. = \frac{5.1 \times 100,000}{6350 \times 0.67}$$

In the calculation of velocity-heads a slide-rule should be used on which the top-scale figures are the squares of those on the lower scale. Using the outlet velocity for No. 1 fan as an illustration I will show how the velocity-pressure in inches of water is quickly determined.

The velocity-pressure in inches of water is $\left(\frac{4200}{4000}\right)^2 \times 1$
Let V. P. = velocity-pressure in inches of water

$$\text{Then, } \sqrt{V. P.} = \frac{4200}{4000}$$

On the lower scale of the rule divide 4200 by 4000. The

FIG. 8

result is the square root of the velocity-pressure so the velocity-pressure is read directly on the top scale of the rule.

To return to the fans, the other horse-powers may be computed in the manner shown. The prices given are those of the fans delivered at the mine. Our next move is to consult the dealer in motors. We are informed that a 150-hp. 3-phase induction motor will cost, with belt, \$2000 at the mine. Its mechanical efficiency is 91% in

FIG. 9

the range from three-quarters to full load. We are now in a position to select the fan in the same way in which we selected the proper size of airway. I shall make the calculation on No. 1 fan to illustrate.

The cost of fan and motor is \$3424.

The yearly capital charge is 12.3% of this, or \$421.

Using an efficiency of 90% for the motor and belt the horse-power required will be $\frac{120}{0.9} = 133$.

133 hp. at \$150 per year costs \$19,950.

The total yearly charge is then \$20,371.

Table No. 3 shows the yearly charges on all of the fans. Evidently No. 3 fan will do the work most cheaply, but how is it that a fan with a mechanical efficiency of 64.5% will do the work more cheaply than No. 1 fan that has a mechanical efficiency of 67%? The reason is this: No. 1 is developing a total pressure of 5.1 in. of water while No. 3 is developing a total pressure of only 4.56 in.; so in spite of the fact that No. 3 has the lower mechanical efficiency, the power required to run it is lower. The speed of the air entering the mine is 1275 ft. per minute, which corresponds to 0.1 in. of water. The total head actually required for the mine is 4.1 in. If we could have all the conditions fulfilled and at the same time get the highest mechanical efficiency it would be ideal, but we cannot. As we go to the larger fans the velocity-pressure approaches that demanded by the mine, but as the outlet-velocity decreases, the ratio of static to velocity departs more and more from 3.64, so the mechanical efficiency decreases. After we go beyond No. 3 fan the increase in power due to the decrease in mechanical efficiency more than offsets the power saved by the lower velocity-pressure and the power to run the fan increases with the size.

If the mine resistance is increased by the extension of the workings the speed of the fan may be increased to produce a higher pressure. If the same amount of air is circulated, the ratio of static to velocity will be still higher and so the mechanical efficiency will be lower.

The velocity-pressure in the air as it leaves the fan is 0.56 in. The velocity-pressure in the shaft is 0.1 in. Unless we can recover this by a gradually expanding duct from the fan to the shaft 0.46 in. will be lost in shock. Using an outlet-velocity that is higher than necessary is uneconomical in the same manner that it is inefficient to compress air to 100 lb. per square inch and use it at 50 lb. per square inch. In the case of the fan we cannot help it.

This problem illustrates the term 'commercial efficiency' which I used some time ago. No. 3 fan, although mechanically not the most efficient fan for our purpose, is from a monetary or commercial view-point the best fan that we could select. In closing this series I desire to thank Prof. B. M. Woods, of the University of California, for his constructive criticism, and R. B. Guernsey, of the American Blower Co., for his interest and material aid in the preparation of these articles.

[This is the last of a series of articles by Professor Weeks on the ventilation of mines. The former articles appeared in the issues of April 24, June 12, June 19, and July 3.—EDITOR.]

Concentration of Magnetite Ore

The whole process of magnetic concentration as applied to the Eastern Mesabi magnetite ore is a good illustration of the manner in which the various machines can be made to work together so as to produce a high-grade furnace-product from an ore containing only 25% iron in the form of magnetite. The hard rock is first crushed to about 3-in. size and is then passed over a magnetic cobber. The field-strength of this cobber is so adjusted that all of the coarse material containing no magnetic iron is

discarded as tailing. The concentrate from this cobber is still too low-grade to be useful, and is, therefore, crushed again to 2-in. size. This material is passed over a second cobber and the worthless gangue again discarded. This process of crushing, cobbing, and discarding worthless material continues until the product has been reduced to about $\frac{1}{4}$ -in. size. When this stage has been reached, approximately one-half the ore has been discarded as tailing and the other half contains practically all of the magnetic oxide that was originally present in the rock. This $\frac{1}{4}$ -in. material, however, still contains too much gangue to be a desirable furnace-product. It is, therefore, crushed wet in ball-mills until it will all pass a 100-mesh screen. This fine material is concentrated by magnetic log-washers in which the final separation is made. The concentrate produced by these machines is then de-watered by the use of continuous filters in the tank of which the fuel for sintering is mixed. The filter-cake is conveyed directly to the sintering plant, where the ore is agglomerated. After being sintered the ore is screened in order to remove any fine material, and only the clean coarse sinter is shipped to the furnaces. It is apparent that in order to make this process a success financially, a large initial investment is necessary. The plant must be built in the most substantial manner, and only that machinery can be used which will operate efficiently and continuously under heavy loads and with little personal attention. At best, the profit per ton that can be made is small, and in order to make the proposition attractive financially, a plant of large capacity is necessary. While this process is a success, from the metallurgical point of view, its financial worth must yet be demonstrated.

The Mesabi Iron Co., according to a recent bulletin of the University of Minnesota, is now undertaking the last stage in the experiment, that is, proving the financial worth of the process. A plant is being built on the eastern end of the Mesabi range, and it is hoped that within a year or two this plant will be in operation and will be contributing its share of ore to the yearly shipment from the district. It is extremely fortunate for the district and for the whole State that responsible individuals, who are willing to expend large sums of money in order to determine whether or not it is economically possible to produce a merchantable material from this low-grade ore, have become interested in this problem.

It is apparent that the success or failure of this first attempt means much in the history of the Lake Superior region. Thoughtful men of the iron-mining industry are watching the progress that the Mesabi Iron Co. is making with the greatest interest. They recognize the fact that failure means a gradual decline of the district, while success means the awakening of a new period of activity. If the hard rock of the Eastern Mesabi containing only 20 to 30% iron can be mined, crushed, and concentrated into merchantable product, it is not difficult to believe that the vast amount of comparatively soft hematite containing from 35 to 45% iron can first be rendered magnetic by roasting and then concentrated magnetically in the same manner as described above.

• By Charles T. Hutchinson •

Those who, from the title of this article, expect to find herein either a learned treatise on chemistry or a recipe for some new viand that defies the H. C. L. will be disappointed. The writer is neither a chemist nor a cook. There is salt and salt. There is the chloride of sodium of commerce, without which popcorn and many stories lack a necessary something to make them satisfying, and again, in mining parlance, there is that ingredient without which many mines would fail of promotion, and many samples would assay of Au nothing, and of Ag even less. Let us then hasten to plunge into the subject, now that the preliminaries are over, and we are settled in our easy chairs and prepared for the worst.

Some philosopher once remarked upon our debt to the great family of suckers, boobs, tenderfoots, and others of that ilk, who view with scorn the modest stock or bond that offers safety and a beggarly 7%, and who instead absorb like a sponge an unlimited quantity of gaudy stock certificates that have back of them nothing whatever but the alluring will-o'-the-wisp of something for nothing. These tender lambkins occasionally back a winner in spite of themselves, and the story of their rise to affluence through the 'investment' of a few paltry dollars furnishes bait for ensnaring new crops of easy marks for generations and generations. Without them, an occasional enterprise of real worth would languish and die; without them a lot of ingenious gents would have to go to work at honest labor.

In the great world of mines and mining, there are names to conjure with, names which have become securely established by lives of honest square dealing, that any enterprise with which they are connected is assured of financial backing from the very start. Mining men of this stamp do not hawk their wares along the highways and byways; theirs are not the ornate, mahogany, and brass equipped suites of offices with thick velvet carpets; they do not surround themselves with those sharp-eyed young salesmen whose eyes are generally too close together and who never look you straight in the face.

Many and devious are the ways of the fake mine-promoter. They would fill volumes if an attempt were made to describe them all, but, fundamentally the difference is nil; all are based upon certain elements of human psychology, greed, the gambling instinct, the desire that lies latent with all of us to get something for nothing, persisting in spite of all warnings of common-sense, and the touch of romance that with the human race begins at the cradle and stops only at the grave. Many men

have made great fortunes by capitalizing their knowledge of these fundamentals, and many more have contributed their mites to the capacious maw of these predatory cormorants of finance.

Once upon a time, there was a promoter. He has now gone to his reward, whatever it may be, but for more than twenty years he flourished, waxing fat or lean, according to the times and the necessity for changing his base of operations after each fresh onslaught upon the treasure-chests of the tenderfoots. He was a survival from the Bret Harte epoch, externally and internally, except that he did not wear a beard. Physically he was not large, but stocky in build, with a deep chest and an iron jaw that bespoke tenacity of purpose.

He spoke two languages, Western United States and profane, the two being so thoroughly admixed as to cause one to think that the latter predominated, which, as a matter of fact, it did. Take the lurid diction of a mule-skinner's vocabulary, add the simple eloquence that would charm a bird off a tree, and you have an unbeatable combination when directed against either the wise men of the East or the unsophisticated denizens of the Middle-West.

Barnum said that the people like to be fooled, and especially do they like their doses of foolery coated with romance, flavored with glittering promises, and washed down with the hope of an affluence gained without exertion on their part. All of these things this mine-promoter furnished, again and again, with little if any variation in method, and with only an occasional change of base. California, Arizona, and Montana were the sites of his various Lost Peglegs, with an occasional incursion to Nevada by way of variety. His crops were harvested in the Middle-West, and even in Southern California, which the rich and idle Easterners make their playground, while the land of Harry Lauder furnished at least one batch of 'canny' Scots whose stock of 'siller' was reducit mair than a wee drappie by a venture in Montana.

He was no wholesaler, this promoter. None of his stocks were hawked about either by salesmen or advertisements. He published neither house-organ nor market-letter. The New York curb knew him not, and the time-worn expedient of wash-sales as bait for the unwary was regarded by him as the trick of a petty larcenist. As a matter of fact, he was an artist in his chosen calling. He was the Caruso of the mining game, a Corot in his masterful command of colorful profanity, an alchemist

in his transmutation of basic quartz into shining coin of the realm.

Always, he was within the law—just within. When the bubble was pricked, and the wails of anguish arose to high heaven from those whom he victimized, they found that they didn't have a leg to stand upon; there was nothing to do but write it off to experience account and shut up. Again he was so very select, as a general rule, in the choice of those whom he invited to "join him in a mining venture", that their very prominence worked against a bleat of any volume. Men of that stamp hate to admit that they have been done, and done brown, with plenty of gravy. Rather do they shut up, pocket their losses, and save their faces from the ridicule of their friends, and, what is even more important, save their reputations as shrewd men of affairs against the undoubted business injury that would react upon them from too much publicity.

How did he do it? Here is a story that is fairly typical. Up the principal street in the financial district of a certain city strode a man of the great outdoors. His tanned face showed exposure to the fierce desert sunshine. His gnarled hands bespoke familiarity with the single-jack and shovel. Over his shoulder was an ore-sack, bulging with specimens. His clothes were well cut without being at all dandified, and he wore them with a vigor and a grace that indicated a muscular body inured to physical activity. Reaching a well-known banking-house, he walked in without hesitation, stopped before the desk provided for depositors, wrote out a check and cashed it. It was during a slack period, and comparatively few people were about the room. Turning to one of the assistant cashiers, who called him by name, he growled, "I want to see the President; tell him I am here". Evidently he was a man who was at least sufficiently at home to command attention.

After a brief period of waiting, he was ushered into the holy of holies. Still clutching his sack of samples he greeted the great man, not in the least overawed by the outward and visible signs of opulence, the oriental rugs, mahogany tables and chairs, and oil paintings of former financial dignitaries that graced the walls.

"How are you, Mr. Promoter?" said the president, with the habitual air of reserve of the money lender, who hesitates to commit himself in advance, on even so trivial a matter as the state of the weather.

"How am I?" growled the promoter, "I'm fine as silk, of course, and why not? Last week we were running a cross-cut on the 100-ft. level of the Horned Toad shaft calculated to cut the vein that made such a won-der-ful showing in the surface croppings, the one I told you about last month. Well, just look at this." With that, he up-ended his sack on top of the president's shiny mahogany table, and a veritable cataract of samples poured forth. Quickly a pocket magnifying-glass was produced, which, carefully freed from dust by rubbing on the leg of the promoter's trousers, was brought into requisition. Silence prevailed for several minutes. One could see the bank president's eye glitter with cupidity.

Here was money, even better, the real thing itself, gold, free gold, sticking out all over. The samples were literally riddled with it. Surely, that ore would go hundreds, perhaps thousands, per ton.

WITH THAT HE UP-ENDED HIS SACK

After a short interval, the bank president brought himself out of his beautiful dream, and his habitual caution struggled for recognition.

"Have you opened this up at all?" said he.

"Opened it up?" ejaculated the promoter. "Why I am in on this thirty feet already, and I haven't struck the foot-wall yet. It is a genuine fissure-vein, pitching about 10 degrees from the vertical, and, you know, a formation of that kind goes down all the way to China, and gets richer the farther down you go. Just as soon as I cut the foot-wall I am going to drift along the vein so as to prove it up, and then put in a raise so as to expose it on all four sides. I consider, from the showing so far, that the Great Horned Toad property is bigger and richer than the North Star or the Empire or any of those others which have been paying big for fifty years."

"Well", said the president, with a sigh, "I suppose you will have to go out and raise some money in order to develop and put in a mill."

"I don't know what I'll do", replied the promoter. "The P. D. & Q. people had one of their experts around the camp when the news of the great showing came out, and they want me to see them today, but I don't suppose they will give more than a half million for it as it stands, and I don't see why I should let them have a mine that will be worth five million or more within a year or so for any such figure as that. What I would prefer is to let some of my friends in on this and divide up with me, so we will all make money and tell that P. D. & Q. crowd to go to hell."

The fly was dangling, and the trout was about to rise. "How much will it take?" asked the banker.

"Well, now", replied the promoter, "I figure that I can enlarge and timber the working-shaft and sink it another hundred feet for about \$8000. Then I must open up and develop about 50,000 tons of ore, which I can do easily with about 500 ft. of additional work under-

ground. Then, while that work is going on we can erect a 20-stamp mill and a cyanide plant, install about 100,000 gallons in water-storage capacity, build a bunk-house and other necessary camp-buildings. I have made careful estimates of the whole business, and," here the promoter paused impressively, "you know I never make a mistake; \$200,000 will do the whole job."

Now spoke the banker, the shrewd man of affairs. "Entirely too much", he snapped. "You ought to get along with about half that. A 10-stamp mill is plenty big enough, and you can add to it from the earnings of the property. Then, why do you have to do so much work underground for the present? Why not get your mill up, and mine as you go along? Make the property pay its own way from the start."

"That's a good idea", replied the promoter. The fish was nibbling at the bait. "This ore is so rich that, even milling only forty or fifty tons a day we can net five or six hundred dollars right along, taking only the poorer rock and leaving the rich ore in place."

"Five or six hundred dollars a day", mused the banker. That was \$15,000 per month, \$180,000 per year. The investment was only \$100,000. Truly, this was a toothsome morsel. Yet, doubt began to assail him. His habitual caution, struggling with the glittering promise dangled before his eyes, clamored for recognition. Then he spoke.

"I suppose you would have no objection to having an engineer go over the property and make an examination", he suggested, hopefully.

"Engineer", snorted the promoter, contemptuously. "Engineer, hell. Old maids in lace-boots, that went to college and write a lot of dam-fool initials after their names, think they can learn about mines from books, spend their time chewing the rag about pseudo-morphs while some goat is paying \$100 a day and all expenses for their time. Then, after they are away a month they write a hundred-page report with ninety-nine pages about the weather, rainfall, and county politics, to say nothing about a lot of bunk on the geology of the district that nobody can make head or tail of, and then, in the last page they say 'Safety First' and turn it down, bill here-with for \$3000, please remit."

"Well", replied the banker, "I'll think it over and see what I can do."

"I leave tonight for Boston", returned the promoter, shortly. "There is a friend of mine there whom I promised to give the first chance whenever I struck anything good. He wants to put up all the money himself, and I have no objection to him, personally, as he is a fine fellow. The only reason I spoke to you about it at all was that I have taken a great fancy to you and would like to put you in the way of making a lot of money for yourself. You could have taken the train back to the mine with me and looked everything over, taken your own samples and had them assayed anywhere you pleased. Then you could have joined me in this venture and looked after it yourself. Of course, you understand, I don't want any money for myself. You can put in your

own book-keeper who will supervise all expenditures, and assure that every cent you put up actually goes into the mine and mill. We can organize a company and you and your friends can have 55% of the stock, which will give you control. I'll put in the mine for the remaining 45%, and you sign a contract agreeing to put up a mill and furnish the money for the additional development work. You don't take any risk at all on that basis. Well, I'm sorry to see you lose this chance." Picking up his samples and putting them back in the sack the promoter took his hat and started for the door.

The banker struggled. One hundred and eighty thousand a year; 55% of the stock. Perhaps he could freeze this innocent, rough, uneducated miner out, and get it all for himself. He gulped a second in indecision, and then, down went the bait, hook, sinker, and all.

"Hold on there a minute", said he. "I didn't say I wouldn't go into it."

"Well, I haven't got any time to waste fooling around here", replied the promoter shortly. "You meet me on the 6:10 train tonight. So long."

True enough, the banker met the 6:10 on schedule time. With him was a lawyer friend, well versed in the intricacies of legal chicanery. In due course of time, after leaving the main line, a 20-mile stage-ride brought them to their Golconda. It certainly was a picturesque camp. A few tents, with flies to fend off part of the fiercest rays of the midday sun, thatched on top with desert willow. In the centre a larger tent, similarly thatched, but open at the sides and end, served as what would now be known as a conference room. In the middle of the tent hung an *olla*, surrounded with moss, and filled with delicious cool water. In the corner were sundry cases of bottled goods, for snake-bites, probably.

BOTTLED GOODS FOR SNAKE BITES

Excavated into the hillside was a storehouse, filled with choice cuts of meat, poultry, and groceries. Every day 500 pounds of ice was packed in burlap, and carried by stage to the camp at a staggering cost.

Hot, tired, and dusty from their long ride, the visitors were conducted to their quarters, where a cool shower and a change of raiment—to say nothing of a real old-time Scotch highball, tinkling with ice, the glass frosted

with the dew—restored good temper, good nature, and a feeling of physical well-being that prepared the stage for the second act in the little comedy, for in those days, the 19th hole was still one up on the eighteenth amendment.

His victims being now regaled and pleasantly relaxed, the promoter brought out his specimens, and for two hours entertained them with tales of the desert, the mines he had opened, the money he had made for himself and friends. He was a wonderful talker, which, coupled with his picturesque profanity, caused kaleidoscopic visions of roseate hue to chase themselves across the imagination of his listeners. Already, they felt themselves fingering the glittering gold-pieces, or shuffling the sheaves of crisp banknotes, all won from Mother Earth.

After a dinner, or 'supper' as it is called, of unbelievable sumptuousness, excellently prepared by the competent cook at \$150 per month, backed by an imported cigar and washed down with the Haig & Haig of our forefathers, the cold canny men of the money market

such as this. The work took several hours. It had to be done carefully and painstakingly, not too much, nor yet too little. It would never do to have the assay too high. That would immediately suggest mining and shipping to a smelter. The mill was what was wanted to play the trick, and \$20, \$30, or \$40 per ton was about right. There are many ways of 'salting', from gold-dust propelled into the face of the orebody with a shot-gun to manipulation of the sample-sacks after they have been taken to the surface, but this particular artist in mineralogical camouflage preferred to plant it where it would do the most good, just like rows of potatoes. His work finally done to his own meticulous satisfaction, he, tired but satisfied, climbed the ladder to the surface, and, in turn, retired to his simple couch, there too, to indulge in his roseate dreams of the first stage in the shearing to take place on the morrow.

Early the next morning, the captains of industry from the busy city were awakened from their glittering dreams by the musical clang of a triangle fabricated out of an

DO WE GO DOWN ON THAT THING?

took to their tents, and were lulled to sleep by the droning of the night-roaming insects.

That night, after all was quiet, our mine promoter took himself down the working-shaft, and then into the old drift and cross-cut. Candle in hand, he went over each inch of face with minute care. He did certain odd and curious things at regular intervals, taking something from his pocket, from a bulging ore-sack in his hand, and apparently planting—what? potatoes? No indeed, 'salt', just salt, in grains and lumps, not the chloride of sodium of commerce, but the good old specimen-rock, obtained from somewhere or other in anticipation of an occasion

old piece of drill-steel and beaten by the efficient Chinese manager of the culinary department. "Bleakfuss he leady. Hot cakee all catchum cole. Hullu up quick fass."

Jumping into their clothes, a quick lick and a promise in the tin basin, and the banker and his lawyer friend made their way to the cook-house with an unwonted spring in their step, a resultant of the fresh early-morning air. Sitting on the rough benches, they did full justice to the grape-fruit, crisp bacon and eggs, followed by hot cakes and syrup prepared by the hands of a master. Oh, the psychology of the full stomach, and the

innumerable men and women who, since the day of Esau, have sold their birthright for a mess of pottage!

Joined by the promoter, who had been up and about before them, their cigars lighted, they hid themselves to the collar of the shaft. There was the usual little head-frame, a 15-hp. gasoline hoist, and a 750-lb. bucket. The two tenderfoots looked askance at the bucket, dangling just at the level of the opening, swaying a little and twisting back and forth. A slight shiver passed over them. Their cigars were suddenly bitter to their taste.

"Do we go down in that thing?" asked the banker, doubtfully.

"Of course you do", replied the promoter. "It is really very simple. Two of us go down at a time. Put your left foot on the edge of the bucket. Hold on to the rope with your hands, and fend off with your foot against the sides of the shaft as you go. I'll do the same on the other side of the bucket, and that balances the weight. Your lawyer friend will come down after us with Mike, the foreman. Come ahead now, let's get started, and you had better put these candles in your pocket."

With many inward misgivings, the banker grasped the oily rope with both hands, and, with one foot, stepped gingerly upon the edge of the bucket. The promoter duplicated this action on his side, and gave the signal to lower. Down they went, the bucket swaying and twisting, the banker trying to recall his boyhood prayers, now long fallen into disuse. After a seemingly interminable period, the bucket fetched up gently at the bottom, and they stepped off and lighted their candles to await the coming of the lawyer and the foreman. Again the bucket rose to the surface and returned, depositing its second cargo of human freight. "Come along", said the promoter, gruffly, "and I will show you the greatest ore deposit you ever saw."

Picking their way gingerly along the drift, they plodded on, the fitful glare of the candles shedding a ghostly light upon their white faces.

"Now, from here on", said the promoter, indicating the wall with his candle-stick, "you can take your samples. For 20 ft. this is all ore. It is all of good milling grade, with a rich seam running through it a few inches wide that will go hundreds of dollars to the ton. Now here", pointing to a series of irregular seams, "is that rich ore, and you don't want to bother with that because that is too high in value. Here are some sacks, and you can take your samples now, or I will take some myself and pan them for you right here before your eyes, so you can see the free gold yourself."

The banker and the lawyer exchanged glances. "We will take some samples and see you pan them now", replied the banker, "and then perhaps this afternoon or tomorrow morning before we have to catch the stage for town we can go underground ourselves and take some samples home for assay."

"That is perfectly satisfactory to me", said the promoter; "go ahead and knock down your samples."

Gingerly they turned toward the wall. Taking their candlesticks they made a few gentle dabs at the rock

and succeeded in loosening a little piece which fell at their feet.

"Hell", snorted the promoter, "that's no way to take samples." He grasped his candlestick, and attacked the wall, apparently at random, with such vim, that in a minute or two, he had loosened enough fragments to make a sizable pile. He gathered it up in a sample-cloth, and carried it to a mortar, beside which was a pan, and a bucket of water. The tenderfoots looked on in rapt admiration. A vigorous pounding in the mortar soon pulverized the fragments. Scooping up a few handfuls he filled the pan, plunged it into the bucket of water, and then the really interesting part of the morning's entertainment began.

THE EXPERT MANIPULATOR PANS THE SAMPLE

With that delicate undulating motion, the expert manipulator began to pan the sample. As if by magic, the coarser particles of ore came to the top and were discarded. Little by little the contents of the pan were lessened, until finally nothing was left but a few table-spoonfuls of fine particles. With a quick twist of the wrist, the sample feathered. There were a few shining grains, that even in the half-light of the candles were different from the rest.

"Here you are", grunted the promoter, holding the pan up to their view.

The two tenderfoots craned their necks forward to see; their mouths open in wonderment. Before their eyes was a little string of particles, perhaps an inch long, shining, glittering gold, the real thing. A sigh went forth from both of them. They licked their chops in eager anticipation.

"How much gold is there?" asked the banker, the man of figures.

"About a dollar and a half", replied the promoter. "This ore is worth about \$100 per ton. I will pan some more."

Quickly putting his thumb over the little thread of gold particles, he plunged the pan into the water with the apparent purpose of removing the result of his first panning before adding another batch, but the thumb over

the gold kept it in place, ready to 'sweeten' the result of the next test. His movements were so rapid that they were not noticed.

Another sample was panned. The resultant gold was nearly twice as much as the first. More oh's and ah's. Again the performance was repeated with the same result. Clearly, this was a marvelous mine. Evidently the promoter was too conservative in estimating its value. Quickly the thought chased itself across their minds. How could they get it all for themselves?

"I think we will get your foreman to help us to take some samples for assay now, while we are down below, so we won't have to come back tomorrow", suggested the lawyer.

"All right", acquiesced the promoter. "Mike, you help these gentlemen take all the samples they want. I will leave you now. Dinner will be ready in about an hour." With that he departed, leaving the embryo miners to their own devices.

With Mike on the job, they delved deep into the surface of the orebody, carefully preserving the samples in the little canvas bags provided by a thoughtful host for the purpose. Each bag was tagged and numbered, although why was not disclosed, as they had no map, nor even a sketch upon which to locate the points from which the samples were taken. However, such is life. The doctor who essays to take his own legal advice, the lawyer who believes in his heart that he is a great architect, and the banker who makes his own mine examinations, are no better than the stage Rube who thinks he knows under which of the three little shells the nimble pea is reposing.

After an hour of toil in the dank depths of the earth, the two tenderfoots, again wafted safely to the surface through the agency of the asthmatic coughing gasoline hoist, took their numerous sacks of samples to their tent for safe keeping until the time of their departure. They did not see the look of inquiry that passed from the promoter to the foreman, nor his solemn wink in return, indicating that all was well.

After brushing the evidence of toil from their clothes, the investors again met the promoter at the conference table, where cool drinks of a refreshing nature were copiously applied where they would do the most good. Soon the stage arrived, and the promoter sent them on their way rejoicing. Why didn't he rush it through before they got away? He was too good a general for that. Too great an eagerness to close before the assays of their 'own' samples had been assayed would have curdled the cream. The time for the hurrah was not yet.

A day, two days, three days elapsed, and then a wire came. "Meet me at my office in two days. Assays satisfactory", read the wire, that brought a grunt of satisfaction from the promoter. Forthwith, he slammed a change of clothing in his bag, caught the next stage for the railroad where he took train for the city, arriving in due course and taking up his quarters in the hotel. Immediately upon his arrival, he phoned the banker and made an appointment for the following morning.

Tomorrow arrived on time, as it sometimes happens,

and promptly the promoter was ushered into the banker's office, and the office boy was instructed that an important conference was to be held and that he was to be incommunicado until further notice. The lawyer, of course, was on the job also, and there in a leather brief case was a mass of imposing-looking documents. Cigars were lighted, and the banker leaned back in his easy backed swivel-chair, fitting beautifully into his surroundings. Here, he was in his element.

"Well", began the banker, "we have had the assays made, and they seem quite favorable. The thing looks good", continued he, deliberately, "and Mr. Lawyer and I will go into the thing in accordance with the general terms you outlined, with certain modifications which I believe you will be wise to accept. Where are those contracts and incorporation papers?"

The promoter took the papers and skimmed over them with apparent carelessness. Stripped of legal verbiage, parties of assorted parts, if's, and's, and aforesaid's, they contracted to furnish the sum of \$100,000, to be placed in their bank for the purchase of machinery and supplies, subject to draft signed by the promoter and countersigned by a secretary to be appointed by the banker. The banker was to O. K. the contract for the machinery and mill construction. A corporation was to be formed with a capital stock of \$1,000,000, of which 45% was to be paid to the promoter in consideration of his deeding the mining property and all improvements thereon to the company. The other 55% was to be given to the banker, the lawyer, and two of their friends in return for advancing the \$100,000 for equipment. This \$100,000 was to constitute a loan to the company, and was to be repaid to the banker out of the first earnings of the company before any dividends were distributed to the stockholders. This was a pretty tight agreement, and the banker was quite pleased with himself in consequence. He waited for the promoter's verdict.

"Well", remarked the promoter, with a grin, "you certainly have this proposition sewed up in a sack. Now", he continued firmly, "there is one thing that I want thoroughly understood. I, and nobody else, am going to buy the mill and install it, and there is to be no interference from anybody. I don't care whether any of you fellows have a nephew, or a son-in-law, or a friend in the machinery business or not. I know exactly what is wanted, and it goes in as I say, or this deal is off right now."

The banker hesitated for a minute. "There is a man to whom the bank has advanced some money who has invented a new process for taking the gold out of rock by electricity, and I would like to give him a chance to put in this plant", he said slowly, "but if you are so set on having your own way, we will let it go. It is too bad, though", he continued regretfully, "for this is a very wonderful thing. There's nothing to it but some kind of a dynamo and some wire, and a magnet. You just crush the ore and then give it a little shock, and out comes the gold. I wish you would change your mind about it."

"You leave that shock business to me", replied the promoter, grimly, "I will take care of all the shocks that go on around that mine. This mill is going to have ten good honest stamps, with plates and a nice little cyanide plant. We will have a power-plant, a good pump, and a hoist with an automatic self-dumping skip, too. This plant is going to work, and work right, and any dam-fool inventor who wants to come around that property and shock my ore is going to take a long ride on the seat of his pants."

That was final. The papers were signed, sealed, and delivered. The funds were placed to the credit of the promoter, and he started for the machinery district to dicker for his plant. One week later he had contracted for his machinery, lumber, cement, and other building material, and, what was even more important, had had himself interviewed by both morning and evening papers. He was a picturesque character, and always good for a stickful of copy. The interviews were corkers. The mine was painted in glowing colors, as being simply rotten with wealth. The reporters played it up with all the language at their command, as they were assured in advance that there was no stock for sale to anybody at any price.

This done, the promoter hied himself back to the mine, and then began a period of feverish activity. Work began on the mill grade, the construction crew was organized. Up went a boarding-house, cook-house, and mine office, in which was installed an anemic-looking secretary selected for the post by the banker. Soon, the first carload of equipment was hauled in, and the new mill began to take form. Quietly, the promoter left for the nearest town and insinuated himself into the graces of the local correspondents for the city papers. He invited them out to the mine. Took them all around, filled them with good things to eat and drink, regaled them with tales of his own prowess, and showed them assay report after assay report of the workings of the Great Horned Toad Mining & Milling Company. When they departed, each with a nice pocket piece of specimen ore, richly sprinkled with free gold, they had material for several Sunday Supplement feature stories.

The promoter organized his publicity campaign with the skill of a master. Every week or ten days, he would drop into town, and feed boost talk to the correspondents. He had just come from the assay-office and would show them the results of the last 10 ft. in the south drift on the 100-ft. level, or he had just traced the outcrop of the vein for a thousand feet or so, and, just see what a wonderful showing it makes, and similar yarns with the same single purpose. Weekly letters to the banker were of the same import. He wafted them along on billowy clouds of imagery; he filled them with dreams of affluence; their nights were replete with beautiful dreams, their days with calculations of profits in six figures.

They talked. They always do. At the club, at the office, at their homes and those of their friends, at social gatherings, even at vestry meetings, there was nothing discussed but that Horned Toad mine, and its wealth.

They were importuned on all sides by friends and acquaintances to be allowed to participate. When the promoter came to the city he was the cynosure of all eyes. He was dined, wine, and feted, and how he did bask in the limelight, and enjoy his brief period of adulation and flattery. Little by little the circle widened. The publicity, advertising, or whatever one may call it was insinuating its way through a constantly growing group of sheep, who were fast approaching shearing. The time was nearly ripe for the grand coup.

In a few months the mill approached completion. Then the day was set for the start, the launching of the enterprise that was to be marked by glittering bars of bullion.

MATERIAL FOR SEVERAL FEATURE STORIES

As the time grew nearer, the promoter was adding many names to a little list in a memorandum book that never left his possession. It consisted of men prominent in the business affairs of the city where lived the banker, and the lawyer, and made up the circle of acquaintances, in one way or another made familiar with the progress of the enterprise, and who had been under the influence of the subtle campaign of publicity launched by the promoter with the unwitting co-operation of his associates. One short week before the time set for starting the mill, a confederate of the promoter called upon him at the mine. There, in the dark of the night, they conferred long and earnestly. On the following day, without flourish of trumpets, the confederate left for the city where the banker and lawyer resided. In his pocket was a copy of the promoters list taken from the little private memorandum book. Also there was a bunch of neatly engraved stock certificates, in small denominations, not more than one or two hundred shares in each.

Upon his arrival at the city, he lost no time. One by one, the men whose names were on the list were approach-

ed. To each, the confederate told the same story. After swearing them to secrecy, he said that he was an old prospector, that he had assisted in locating the Great Horned Toad mine, that his share of the property was represented in so many shares of stock. Here, he exhibited a certificate that had been duly endorsed over to him by the promoter. He was hard up, broke in fact, and, although he understood that it had turned out to be a great property, he simply had to sell. Wonderful opportunity, a chance to slip one over on a man hard up, and who would have to accept most anything that was offered. He was shrewd however, this innocent hard-up prospector. He stuck out for a fair price, and, in almost no case did he take more than 10% less than par. So well did he do his work, so quietly did he go from man to man on the list, that he was cleaned up a day or two before the time set for the starting of the mill. Then a wire, a few cryptic words to the promoter, and a visit to another bank, the purchase of New York exchange for the entire amount, and it was considerable, and he caught a train for Broadway.

The day of the grand opening had come. The stage was set. The mill finished, the banquet table arranged for the banker, the lawyer, and their friends who were approaching the mine in special stages chartered for the purpose. The table fairly groaned with good things.

THE TABLE FAIRLY GROANED WITH GOOD THINGS

There were whole baked hams, cold turkeys, salads, relishes, superb hot biscuits prepared by the Chinese cook, a master of his profession. There at the side of the open tent, were tubs of bottled beer, surrounded by chunks of ice. In other tubs were pieces of cracked ice to add the necessary fillip to the famous Scotch, for which long glasses were provided. The table was set for forty, and as the first of the special stages rounded the turn, it appeared as if everybody had come.

There was the new mill, clean cut and beautiful to the eye. There the head-frame, there the new power plant, with the business-like smoke pouring from the stack. As the last stage came into view, the whistle blew, a loud discordant note proclaiming the advent of the conquering heroes, to whom the perils of the desert were as nothing.

Welcomed to the mine by the promoter, who was wreathed in smiles, they were conducted to the primitive wash-basins where they removed the stains of travel. Then the feast, that wonderful feast, that was like nothing

else they had ever experienced. Filled to repletion, they lolled back on the benches, their cigars lighted, and listened to an impromptu address from the promoter. He told them lovely things about themselves, how great they all were, of the great debt that civilization owed to them, those pioneers of the waste places. He told them about the mine, as only he could, how rich it was, and how rich it would make them. Then he took them underground in batches and showed them around. He had put a round of shots in the roof of the drift making passage next to impossible. There they were, all dressed up, at times crawling on their hands and knees, and even tummies, candle in hand, down in the bowels of the earth, wishing they were safely topside once more.

This finished, they were conducted around the mill. They admired the imposing battery of stamps, they inspected the mysteries of crusher, automatic feeders, concentrating tables, the rows of tanks the purpose of which was to them a profound mystery. Then, at a given word, a rumble, then a creak, then a hum was heard. The darn thing was running. The breaker began its crunch, crunch, and the broken rock began to fall into the bin. Then the roar of stamps was added to the din, and soon, a watery mud began to trickle through the battery screens and run down over the plates. Then the concentrators began to shimmy, the filter revolved, in short everything was a grand success.

"I don't see any gold," anxiously remarked one of the guests. The promoter regarded him pityingly. "We always start up with waste until everything is running smoothly, and the adjustments are made," he replied. Satisfied, pleased at this exhibition of foresight, the guest retired. Taking the banker aside, the promoter said, "Tomorrow I will turn everything over to the superintendent you picked out, and who is due here in the morning. I am tired out with my hard work getting this mine started, and I am going to the seashore for a couple of weeks."

Surely, he was entitled to a rest, this hard worked miner. The banker acquiesced with a smile. He remembered his instructions to the new superintendent, "Run her for a week and then shut down for any reason you like. Then we will declare a series of assessments until we freeze that old duffer out."

The guests departed. The next morning the new superintendent arrived, and was met at the stage landing by the promoter, all packed, bag and baggage, ready to take the same stage out. "I am leaving everything for you with the book-keeper. You are in full charge and will report for instructions to Mr. Banker. I am going to the seashore for a rest. So long", and that was all. But, the promoter did not catch the train for the seashore. On the contrary he caught the Limited for the East, and, in course of time, at a well known New York hostelry, he met the hard-up prospector, now miraculously metamorphosed into considerable of a dandy, who greeted him warmly, almost affectionately.

The two retired to a room, where an interesting ceremony took place. It consisted of a division of sundry bright looking documents, New York drafts aggregating

a sum of money running into six figures. Let us leave them for the present, and return to the Great Horned Toad mine, and follow the new superintendent around.

This new superintendent was a competent man. He seemed to ignore the beautiful new mill, the mine office with its imposing sign, or the other surface indications of something, whatever it might be, at depth. He went immediately to his quarters, changed to his digging clothes, proceeded to the hoist house, and gave orders to be lowered. Candle in hand, accompanied by the foreman, he plodded through the short drift, crawled over the material which had been broken from the roof in preparation for stoping operations. Every few feet he stopped, looked, and listened for any explanation that the foreman might offer. None was forthcoming. Silently he continued on his way, and reaching the end of the drift, he turned, retraced his steps, and was hoisted to the surface. Immediately he gave orders to shut down the mill.

His lunch was eaten in silence. Then he sent for the foreman, and said, "We are going to sample this property immediately, as best we can. Get a couple of men with drills and get underground at once. I will show you where I want the shots put in."

For three days, the men were busy putting in the holes. Then they were fired, and the result carefully hoisted to the surface, crushed, quartered, and delivered to the assayer. A day or two later came the reports. Assay after assay revealed the cold, pitiless fact that of Au there was from a trace to 49c., and of Ag there was nothing that could be determined. In order that no stone might be left unturned, the superintendent then sampled the crop-pings, as far as he could trace them. The result was the same. There was nothing there, nothing but just plain ordinary country rock. The dose was not palatable. It lacked the pinch of salt.

Gathering up his documents, the superintendent caught the first train to the city. Upon his arrival he met the banker and the lawyer in the former's office, and there, quietly and in simple language, he told those two shrewd business men that they had been stung, that they had been bamboozled to the Queen's taste, that there had been nothing there, and that there was no indication that there ever would be anything there.

Shock, followed by consternation, then wild rage against the promoter who had dared to assault these hitherto impregnable treasure chests, oh! the language that rose to the high heavens, as they called him everything they could think of. They would have him arrested; they would send him to the penitentiary for life. Then the lawyer remembered that they had no grounds whatever for any action. He remembered that of all the crimes on the Penal Code, there was not one single one that they could pin on that wily promoter. They had been salted. Of that they were sure, otherwise how could those marvelous assays be accounted for, but of evidence, there was not one jot or tittle. They knew that the samples that had been assayed could not possibly have come from the 'Great' Horned Toad, but prove it they could not. There was no more. Of that they were sure.

Telephone calls from their circle of friends asking anxiously when the first clean-up would be made, first created suspicion, and then certainty, that the promoter had unloaded his stock at good prices through their own unwitting connivance. Little by little, as they began to recall the facts, all the circumstances reassembled themselves in their minds, and they realized to the full, their folly, and how cleverly they had been done. Analyzing the whole scheme for flaws in their own procedure, the banker, some months after, was heard to remark, "Well, I suppose it would have been better for me to have sent an engineer to examine the property before we got in so deep, but, anyway," this to himself, consolingly, "I saved two or three thousand dollars in engineers fees." His friend, who had been listening, asked with a smile, "And how much did you lose without the engineers' services?" The banker, startled out of his calm, answered "One hundred thousand". Then he saw the drift of the question. "Oh, go to hell," he snorted.

THE IRVINEBANK smelting works, in North Queensland, which were taken over by the Government last year for a period of 3½ months, up to December 31 produced 35 tons of tin valued at £11,770. The Government battery at Bainford treated during the year 1070 tons of tin ore, and 253 tons of ore containing wolfram, molybdenite, etc., and the recoveries were: black tin, 25 tons, valued at £3308; wolfram and bismuth, 44 tons, valued at £9783; bismuth, £112; or a total of 90½ tons of concentrate, valued at £19,915. The plant is being further improved by adding to the storage capacity of the bins and by the addition of a magnetic separator for the purpose of separating bismuth and wolfram. The plant worked two shifts during the greater part of the year. The report of the Secretary for Mines states that the acquisition by the Government of the Chillagoe smelters, railway, etc., has led to a great revival of industry in that locality, as well as at Mungana and Einasleigh. About 75% of the ore supply for the smelters is expected to be derived from the last-mentioned mine. It is expected that the regular output of the works will be at the rate of about 200 tons per month. The complete return for March was: 153 tons of blister copper, containing 151.3 tons of pure copper, 7650 oz. silver, and 111 oz. gold; also 280 tons lead bullion, containing 272 tons lead, 16,880 oz. silver, and 39 oz. gold.

Electro-Metallurgy of Manganese Ore

Bulletin No. 5 of the Engineering Experiment Station of the University of Washington, 'Electro-Metallurgical and Electro-Chemical Industry in the State of Washington', by Charles Denham Grier, gives the following brief description of the process in use at the ferro-manganese plant of the Bilrowe Alloys Co. at Tacoma. In this plant, manganese ores from Philipsburg, Montana, are mixed with sufficient coke for reduction, limestone for fluxing, and a little metallic iron, and then smelted in six single-phase open-top shaft furnaces. Each furnace has a capacity of a little less than two tons per day when operating on the best ores. Four of these furnaces are enclosed in shells of $\frac{3}{8}$ -in. boiler-plate, 77 in. diam., 69 in. high, flanged at the top, with a 6-in. strip of brass running from top to bottom to break the magnetic circuit. The shells are cooled by a water spray from a perforated pipe that encircles the shell near the top. The other two furnaces are of reinforced concrete, 7½ ft. square on the outside with a circular central shaft 79 in. diam. The lining of both kinds of furnaces is the same. At the bottom is a water-cooled cast-iron grid, which is embedded in and under the rammed mixture of ground carbon, graphite, and coal-tar that forms the bottom of the crucible. The side-walls of the crucible are made of California magnesite and extend up above the smelting-zone. Above this, the lining is of hard-burned firebrick, which will best withstand the abrasive action of the charge and of the poking necessary to ensure proper descent of the charge.

The two concrete furnaces each have a guide, which extends from the sides and across the top of the furnace to hold the electrode in the centre of the shaft. The other furnaces lack this feature, and their electrodes are merely supported by steel cables from a car-truck overhead. In all except one furnace, 16-in. square, amorphous carbon electrodes are used; in that one 20-in. round electrodes of the same material are used. The electrodes have threaded recesses in each end and new lengths are joined to the electrode in place by means of a threaded plug screwing into both pieces. A paste of graphite and raw linseed oil is used between the surfaces to increase the conductivity of the joint. Putting on a new length requires from ten to fifteen minutes with the concrete furnaces, but from one to two hours on the other furnaces.

The electrode-holders are in two parts, which clamp on the sides of the electrodes. They are water-cooled. The flexible water-connection required is an asbestos ½-in. steam-hose. These holders have arms that extend past the side of the furnace where the clamps which make connections with the leads are bolted on. A counterweight balances this eccentric weight. Some trouble has been experienced with the holders, as the electrode faces are irregular and good contacts are not made over the entire surface. This results in hot spots, which eat away the carbon, sometimes producing an arc that attacks the cop-

per, and frequently allows the suspended electrode to drop into the bath.

The power required for each furnace is approximately 350 kilowatts. The current is supplied to the terminals of the furnace at about 55 volts. The power factor is said to be about 90%. The conductors to the furnace, which are ¼ by 6-in. bars, are placed close to each other to minimize reactions, and the magnetic circuit in the shell is opened by the strip of brass mentioned before. The energy required per long ton of product is said to vary between 4600 kilowatt-hours, which is the amount used when running on the best ores, to an average of 5500 kilowatt-hours, which was the figure obtained over a period of four months while using the different grades of ore shown below. Power is purchased at rates varying with the load factor, and this is usually such as to earn a rate of from 3.31 to 3.52 mills per kilowatt-hour. Under the power contract, the plant is subject to shut-down in case of low water. During the past two years it has lost approximately ten days together with three or four minor interruptions.

The following analyses represent the different grades of Montana ore used:

	Mn %	SiO ₂ %	P %	Fe %	Al ₂ O ₃ %	Moisture %
Concentrate	49.13	9.4	0.081	1.0	2.7	10.3
Washed ore	42.07	20.2	0.092	1.3	4.0	12.2
Coarse good ore.....	47.08	15.08	0.055	1.2	3.0	5.81
Coarse poor ore.....	38.27	23.4	0.077	..	6.0	9.55

The concentrate is fine and tends to pack in the furnace so tightly that the gases formed by the furnace reactions cannot pass freely. The result is that gas accumulates until the pressure is high enough to force a passage, which is usually along the electrodes, through which it 'blows' with considerable force, materially shortening the life of the electrode. To minimize this trouble, coarse ore is mixed with the concentrate in equal quantities. It is also found necessary to mix the ores so that the Al₂O₃ content does not exceed 4%. Ores exceeding this amount yield a slag which does not separate well from the metal, which is entangled in, and clings to, the slag when cool.

Typical analyses of the ferro-manganese and the slag produced are as follows:

Ferro-Manganese		Slag	
	%		%
Manganese	80.03	Manganese	13.97
Iron	11.5	Ferrous oxide	1.2
Silicon	0.6	Silica	34.7
Phosphorus	0.274	Lime	35.8
		Alumina	4.6

The ingredients of the charge are bedded in small bins and are mixed by shoveling into the charge-cars which carry it to the furnace. The furnaces are fed continuously and are kept poked down at all times except during the 20 minutes before tapping. It is desirable to have the furnace crust over before tapping so that no imperfectly separated material will be tapped out. The ferro-manganese and slag are tapped into shallow cars every two hours, allowed to cool for several hours, after which slag and metal separate along a clean line if the charge has been correctly proportioned and the alloy is ready for shipment.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

DRILLING CONTESTS AT JEROME.

GLOBE.—The Old Dominion company has developed high-grade ore on the Maggie vein, north of the 'A' shaft on the 19th level. Assays running from 10 to 34% have been reported. The company is now cutting a station on the 20th level, which will automatically drain the 19th and permit active development on the Maggie vein at that level. Production for the month of June was considerably in excess of that for the month of May, which amounted to 2,287,000 lb. of copper.

It is reported that the Arizona Commercial has opened rich ore in its raise that is up a distance of 85 ft. from the 1600-ft. level. This is now within 15 ft. of the 1500-ft. level and practically assures the company 100 ft. of ore yielding in the neighborhood of 10% copper. On the 4th level, where commercial ore was recently found, drifting continues with the orebody which shows no diminution in size or quality. The company is producing 600,000 lb. of copper monthly at a cost of approximately 14c. per pound.

During April, according to monthly bulletin sent to stockholders by Frank P. Knight, president, the production of the Iron Cap Copper Co. amounted to 654,125 lb. of copper and 8807 oz. of silver. The mill is operating satisfactorily and production is estimated at about 300 tons per day. It is said that on June 9 the Supreme Court of Maine handed down decisions in the suits brought by the Arizona Commercial company. In the apex-case the bill was sustained. Counsel for the Iron Cap has asked for a re-hearing.

BISBEE.—The ventilating shaft which is being put down in the neighborhood of the Briggs mine of the Calumet & Arizona Mining Co., has reached a depth of 300 ft. An average of more than eight feet per day has been attained since the work began, and during last week 54 ft. was sunk in six days. When completed the shaft will be more than 800 ft. deep. The company is installing two more boilers which will give the boiler-plant a total of 15. The increased capacity is for use in handling the increased flow of water that is expected to develop as the Junction shaft is deepened. Plans for sinking the Junction shaft from the 1800 to the 2200-ft. level are now under way.

SUPERIOR.—Announcement has been made that John Fowle, vice-president and general manager of the Silver King of Arizona Mining Co., has been appointed receiver of the company by the Superior Court. It appears the

Silver King company is having difficulty in financing property and Mr. Fowle will keep the water pumped out of the mine and look after the property generally.

JEROME.—Unusual interest was aroused by the drilling contests held in the town of Jerome during the two holidays on July 4 and 5. Contests in both hand and machine-drilling were held. Seven teams of two men each, entered for the machine-drilling contest, two from the United Verde, two from the United Verde Extension, and one from the Jerome Verde. A large block of granite was brought over from the famous granite mountains of Prescott, expressly for the purpose. The betting was fast and furious and several thousand dollars changed hands before the United Verde teams were declared the winners of both first and second money. The first prize, which amounted to \$250, was won by Navarette and Navo, of the United Verde. The winners showed them all a trick by making but three changes of steel in drilling the last hole instead of four changes as made by the other competitors. Each team was required to drill two holes, one above, and one below the bar, and the program for each team was to set up the standard, attach the bar, connect air and water-hose, drill a 5-ft. hole, turn the drill under the bar, and drill another hole.

The time taken by each team is as follows:

Team	Set up	1st hole	Change	2nd hole	Total
Gerkovich and Milich	2:32	6:06	1:11	4:59	14:48
Gomez and Lopez	2:16	7:06	1:38	6:21 ½	17:21 ½
Vincente and Mendiaz	2:05	7:59	1:20	7:19	18:43
Lopez and Fernandez	1:47	7:21	0:50	6:34	16:32
Navarette and Navo	2:03	6:28	0:56	4:54 ½	14:21 ½

The quickest set-up was made in 1 min. 47 sec., while the longest took only 2 min. 32 sec. Ordinarily it takes a man from 20 to 40 min. underground to set up and prepare to drill his first hole.

Four teams entered for the double-jack hand-drilling contest: Townsend and Slade from the United Verde, Lopez and Gomez from the Jerome-Verde, McKinnon and McKinnon from the Grand Island, and Schull and Wolf from Turkey. Thousands of dollars were wagered on the contest. The results were as follows:

McKinnon brothers	31 ½ inches
Schull and Wolf	29 "
Lopez and Gomez	27 ¾ "

Immediately at the conclusion of the contest Schull and Wolf challenged the winners to another competition for a purse of \$500 and the McKinnons not only accepted the challenge but suggested that they still had another \$500 and would like to wager it as well. The local record is 35 ½ in. and the State record is 39 ¼ in., made 12 years ago in Bisbee.

CALIFORNIA

SEVERAL MINES IN NEVADA COUNTY SUSPEND OPERATIONS.

AMADOR COUNTY.—The water level is being lowered slowly at the Argonaut mine. The pumps are now working smoothly. Tanks are also used in hoisting water. No move has yet been made by the Kennedy company to operate its plant although the hoist has been completely overhauled and placed in readiness to commence at any moment. From what the public can learn it is believed that a move will be made shortly by the Kennedy people to bear their part of the expense in draining the underground workings. At this writing the water has been lowered about 65 ft. below the 3100-ft. level.

In cutting a station at the bottom of the recently sunk section of the shaft at the Plymouth Consolidated mines, a body of high-grade ore, assaying \$70 per ton, was uncovered. Just what the length and width of the new find is, cannot be known until further development is done, but 16 ft. of ore has already been cross-cut. The find is important and comes at an opportune time. The ore hoisted from drifting in the 600-ft. winze in the Bunker Hill mine, from which so much was anticipated, is so low-grade that it goes over the dump. Prospecting still continues. The Keystone at Amador City is doing nothing beyond keeping the mine drained.

NEVADA COUNTY.—The controversy which has existed for a number of months between the North Star and Empire Mining companies and other users of water and the Pacific Gas & Electric Co. was recently decided by the Railroad Commission in favor of the water-users. The latter company sought to compel the water-users to change to electricity necessitating the expenditure of many thousands of dollars. After years of operation the North Star Mines Co. has decided to abandon the Champion mine on Deer creek, a mile below Nevada City. The property consists of a large area, the greater portion of which has been acquired as the result of litigation with the Home Mining Co. and other properties, due to alleged charges of trespass, and on account of a complex vein system. The mine operated two shafts and was equipped with a 40-stamp mill and a cyanide annex. Formerly the mine was a producer but of late years small bodies of ore encouraged continued prospecting until within the last year. High costs and lack of ore-reserves have compelled the company to close permanently. Nevada City is thus left without a single quartz mine within its immediate vicinity. A force of men is already at work dismantling the machinery and buildings.

R. H. Long of San Francisco stated that the old Excelsior mine at Meadow lake will be re-opened shortly, treating the ores by the cyanide process. The Golden Gate mine, idle for some time, has been abandoned. It adjoins the Idaho-Maryland property. Operations at the Lily have come to a temporary standstill pending a better understanding among the stockholders. George Mainhart of Nevada, Harvey I. Miller of Salt Lake City, George Packard and J. S. Oiler of Boston, have recently been looking over the Mother Lode section and the Grass Valley district.

PLACER COUNTY.—The Rising Sun mine at Colfax has commenced mining in earnest, the 10-stamp mill treating ore of ordinary grade. The ore is automatically handled from skip to mill.

COLORADO

'DOLLAR' SILVER IS REVIVING COLORADO DISTRICTS.

CRIPPLE CREEK.—Old mines and old miners are making good: as a result of recent work two rich gold discoveries have recently been made. The first was at the Strong mine, Battle mountain, near the surface, and the second, at a depth of 750 ft., on the American Eagles property, located personally by the late W. S. Stratton. An 'old timer', George Furst, has opened up a rich vein, on the upper Strong fraction, immediately adjacent and cutting into a later location the Queen of the Hills, of the Portland company. Samples taken across 2½ ft. of vein matter, have returned \$75 to \$800 per ton. Furst has taken out about 45 tons and his first shipment will be loaded next week. He will install an electric hoist if returns are as good as the assays.

The second discovery has been made by F. M. Kurie, former superintendent of the Portland company, who has been mining and shipping a good grade of milling ore from two blocks of the Stratton estate, Bull hill, operated through the Star of Bethlehem shaft. He recently secured a modification of his lease whereby the depth was extended and he was permitted to operate from the American Eagles deep shaft. By a short cross-cut Kurie has opened up, if not the vein he was seeking, one with better prospects as two drifts now being run on the vein have both breasts in ore and samples show four ounces gold per ton.

A vein of altered granite, not hitherto cut on the property, has been found in sinking the Empire State shaft of the Isabella Mines Co., below the 900-ft. level station. The vein has two streaks, two feet apart, that sample \$30 to \$50 per ton. It has a north-west strike and dips strongly to the north-west. The shaft is to be continued to the 1500-ft. point. Development work at the Last Dollar shaft, Modoc Consolidated Mines Co., is centred in the long cross-cut through the Combination claim, to the north-west. This cross-cut when completed will be 2400 ft. in length, with cross-cuts at intervals to exploit this undeveloped territory. The cross-cut should cut every known vein and dike that traverses this claim. At the 1200-ft. level, three veins are under development in ground south and east of the shaft.

GELPIN COUNTY.—A rich strike has been made on Idaho hill, on property adjoining the old Mackey mine, by the Elk Park Mining Co., a Denver corporation. At a depth of 200 ft. the Annie H. vein, first opened in an upper shaft on the property, has been cut and samples assay two ounces gold, 16% copper, and two to five ounces silver per ton. In addition there is 2½ ft. of mill-ore assaying \$11 to \$13 per ton. The company has a stamp-mill on the property but plans to install a flotation unit to handle the sulphide ore.

GEORGETOWN.—A recently organized Wisconsin com-

pany, the Brown Deer Mining Co., is starting work on the Reindeer lode near Silver Plume under management of Thomas Buxton. Operations have been resumed in the Cutley tunnel near Berthoud pass and on the property of the Republican Mines Co. Contractors have started an extension of the Clinton tunnel.

CENTRAL CITY.—Smelting-grade ore has been opened up on the Annie H. mine at Apex, above Black Hawk. The streak measures eight inches, in addition to some mill-ore. Operations have been resumed on the Evergreen property, and the milling-plant is shortly to resume treatment. The Rochester tunnel of the Saco de Oro company has been re-timbered and work resumed in the breast, where streaks of galena have made their appearance. The tunnel is heading for the discovery shaft, where rich silver-lead ore formerly was mined. Silver-bearing ore has been opened up in the Yankee Hill district by owners of the Saunders-Gobelman property. The Chase mine is to be unwatered and the shaft sunk 100 ft. from its present depth of 450 ft. The Rara Avis, a silver-lead producer, one of the richest mines of the earlier days, has been leased to Kansas parties. The property has been in litigation some 30 years and has been closed for this time. The shaft is 550 ft. deep but in unworkable condition and a tunnel already in 600 ft. will be extended to cut the shaft at the 300-ft. point. The property according to the records has produced ore running as high as 1300 oz. silver per ton, and ore is reported by 'old timers' to be still exposed in the lower workings.

LAKE CITY.—A contract for 1000 ft. of work in the Hidden Treasure tunnel has been awarded to local miners and work has commenced. An aerial tram is to be constructed from the Cleveland tunnel to an ore-house under construction on the county road, thereby reducing the haulage to the shipping point on the D. & R. G. railroad. The lessee on the Fannie Fern on Benson creek is shipping silver-lead ore of high value to the smelter. The Mountain Chief group near the Fannie Fern is being operated by the Standard Mines Development Co., a common-law trust recently organized by G. R. Harkness, prominent mining man of Hinsdale county, and Denver men. Ore is exposed in tunnel-workings that assays as high as 472 oz. silver and 1.63 oz. gold from the foot-wall streak, with fully six feet of milling ore in addition. In the shaft workings, ore assaying as high as 640 oz. has been mined, and a tunnel is now projected to cut the vein at depth. Dollar silver is proving an incentive to silver mining and a number of Hinsdale county properties have recently been examined.

SILVERTON.—The Early Bird property owned by C. B. Mitzikie of Silverton and operated under bond and lease is producing high-grade gold-silver ore. A recent shipment of sacked ore, of small size, netted the operators \$1470. A second shipment of rich ore will be made soon. The Bagley mill has been bought under writ of execution by C. B. Blitzkie and will be overhauled and put in condition to treat custom ore. The Gnome Mining Co. has increased the working force at its properties at Animas Forks, where development is in progress.

MICHIGAN

OUTLOOK FOR THE COPPER PRODUCERS NOT IMPROVING.

The coal situation continues to be the most important problem for every copper mine in Michigan. The problem is in no wise helped by knowledge of the fact that there is no hope for any reduction in prices, and there is doubt whether coal in sufficient amount can be secured even at the present going prices. To add to the prevailing pessimism there is the continued shortage of labor and the fact that there is little evidence in present shipments of an increased demand for the product of the mines.

Wolverine is going to show an improvement in the content of its rock this month, and what is now going to the Wolverine mill contains 20 lb. per ton. Wolverine No. 4

MASS COPPER IN THE QUINCY MINE, MICHIGAN

shaft is shut-down temporarily. The tonnage is increasing from No. 3. The Wolverine stamp-mill is idle for a few weeks to make repairs to the rock-bins, and the Wolverine ore is being cared for at the Mohawk mill. The tonnage now is coming from the 38th level and the four levels above, including the foot-wall, arches, and pillars. Wolverine now is holed-through to the North Kearsarge so that it is not necessary to handle the extra water which has been coming from the South Kearsarge.

Seneca's shaft now is approaching the 5th level. The 3rd and 4th level drifts are being pushed to the property limits, with the thought of securing greater lateral distance before further stoping. This policy makes it necessary, temporarily, to forego the increase in tonnage anticipated. Under existing conditions of the market this is not objectionable. Development work in the Gratiot shaft is exposing much barrel and small mass material. Mohawk is securing considerable silver from points below the 16th level. It does not appear in nuggets, the particles being quite fine, recoverable only in the smelter.

MONTANA

LUMP GULCH MINES ARE SHIPPING TO THE PLANT OF THE NEW YORK-MONTANA TESTING & ENGINEERING CO.

MARYSVILLE.—A new 5-ft. fissure has been opened on the 400-ft. level of the Shannon mine of the Barnes-

King Development Co. The ore assays \$14 per ton in gold.

HELENA.—Another high-grade ore-shoot has been opened at the Vera Cruz mine in the Lump Gulch district after drifting west and cross-cutting to the south from the 4-ft. orebody recently reported. The new ore-find strikes with the first discovery and shows similar assay values, namely, 5% copper, 78 oz. silver, 1 oz. gold, 18% lead. M. J. McEvans is superintendent. Ores from both the Liverpool and Monarch mines are now being treated at the plant of the New York-Montana Testing & Engineering Co. Plans have already been completed for increasing the output of this plant.

NEIHART.—Practically normal conditions are prevailing in most of the mines in this district. The Hartley mine is employing 18 men. Ore is being taken out from two stopes on the 300-ft. level. At the Silver Belt and Blackbird mines, similar conditions exist. Twenty-two men are employed. Development work is being completed to connect the two mines and thus reduce haulage costs. On the 200-ft. level of the Silver Belt, a 4-ft. vein has been uncovered. The ore is said to run 50 oz. silver per ton and 35% in lead. After a second walk-out at the Flohart mines, the men have returned and promise to remain regardless of any further action by the labor union. The wages and conditions are satisfactory.

NEVADA

ADDITIONAL TIME GIVEN IN SALE OF SILVER HILLS MINE.

TULE CANYON.—Three stamps that crush 10 tons each daily have been added to the five light stamps in the old mill at the Silver Hills, giving a total capacity of 40 tons. Ore is being stoped from above the 50 and 100-ft. levels and the mill-heads are maintained at 40 oz. silver. The concentrate assays 1000 oz. The west drift on the 50-ft. level is 85 ft. long and the east drift is 75 ft. long. The west drift on the 100-ft. level is 65 ft. long and the east drift is 90 ft. long. There is an 8-ft. width of 106-oz. ore on this level. The shaft, which is being sunk from the 100-ft. level, has passed out of the vein and a cross-cut will be driven at 200 ft. The condition of the vein at 200 ft. will decide definitely whether the sale will be concluded and Ingalls and Mercer, the owners, are so confident ore will be found that they have extended the time for the second payment from August to December. Neither ore nor concentrate has been shipped since the Silver Hills started work. There has been found on the 50-ft. level a piece of almost pure silver five inches in diameter. This was sent to the New York office of the company. The inclined shaft now being sunk is single-compartment, but if ore is found at 200 ft. a double-compartment vertical shaft will be sunk and electric power will be secured from the line of the Nevada-California Power Co. at Palmetto. Thirty-five men are employed.

WEST DIVIDE.—Work has been resumed in the West Divide after a shut-down of two weeks caused by lack of funds. L. L. Patrick, promoter and manager, says he has been assured by Zeb Kendall, already heavily interested,

that he will furnish additional money sufficient to prospect the vein at a depth of 150 ft. An inclined shaft was sunk 65 ft. in the vein and drifts were driven with good results. An old tunnel was then extended and a vein was cut south of the shaft at a depth of 150 ft. This vein was supposed to be the same as that in the shaft and a drift was driven toward the shaft without opening ore. When the drift reached a point under the shaft a re-survey showed the possibility that the work had been done in a parallel vein and a cross-cut was started to find if this were true. This cross-cut is now 65 ft. long. It will be advanced 10 ft. more and if another vein is not found a raise will be driven from it.

DIVIDE.—Work has been stopped at the Alto and East Divide because of lack of funds, according to J. K. Turner, consulting engineer for both companies. There is 300,000 shares of stock in the Alto treasury, but to continue work it would have been necessary to sell this at one cent or less per share. "We can't interest anyone now and intend to let the affairs of the company rest," Mr. Turner said. The Eastern stockholders in the East Divide are reported to have a plan to re-finance the company without levying an assessment. Sinking of the Sutherland shaft has been stopped at 900 ft. and lateral work has been started at this depth. At a meeting of stockholders in the Belcher it was voted to reorganize the company on an assessable basis. The shaft of the Gold Zone, being sunk from the 500-ft. level, is nearing 800 ft., where an attempt will be made to find the extension of the Tonopah Divide ore-shoots, which, according to engineers, will be found in the Zone at this depth. The Kernick, a short distance west of the Tonopah Divide, is planning to sink to 1000 ft. from the present depth of 500. It is said that before the present management took charge the main south-east drift on the fifth level of the Tonopah Divide was in error turned from the main vein and driven outside the vein to the Gold Zone boundary line. This is the most recent development in the efforts of George H. Garrey and William Watters to determine what became of most of the \$9,000,000 worth of ore that A. I. D'Arcy estimated was in the mine in July of last year. Reports say the main vein has been found in a cross-cut from the drift and engineers take this as an indication that perhaps the future of the mine is not as black as it has been painted in recent months. A drift on the third level has been driven 50 ft. in a vein parallel to the main one, the ore for the width of the drift assaying more than \$35 for this distance. This vein has not been cross-cut.

RAILROAD SPRINGS.—The 70-ft. shaft of the Silver Coin has been cleaned, a hoist and head-frame are in place, and it is planned to sink the shaft to 100 ft. before drifts are driven. J. K. Turner, consulting engineer to the company, estimates that there is four carloads of \$60 ore available for shipment through Goldfield, 23 miles north. The Silver Coin is being developed under lease by the Crescent Divide, which has \$4000 to \$5000 in the treasury.

GOLDFIELD.—Work from the 815-ft. level of the Grand-

ma has been stopped and sinking of the shaft has been resumed. The Great Bend, after driving around caving ground on the 375-ft. level, is cleaning the raise from this level and when this has been completed drifting from the raise will be resumed. Ore 6 to 9 in. wide and assaying \$315 for a distance of 12 ft. has been found by a lessee on the 60-ft. level of the old Patrick-lease shaft of the Lone Star. No work was done south of the shaft by the early-day lessees and the ore was found by drifting 8 ft. in this direction. Work has been stopped on the 60-ft. level, with the face of the drift in rich ore, and a drift is being driven at 80 ft. The company has started work at 220 and 250 ft. to search for the same shoot. When this ore is shipped it will be the first to come from the Lone Star

this city on July 13. Representing the Commission were Huston Thompson, chairman; Claude R. Porter, chief counsel, and Gaylord R. Hawkins, assistant counsel. Among the mining men who were called to testify were Frank J. Westcott, secretary of the Silver King Coalition Mines Co.; Geo. T. Hansen, of the Midvale Minerals Co.; Geo. W. Lambourne, president and general manager of the Judge Mining & Smelting Co.; O. J. Salisbury, president of the Ramshorn Mining Co. of Idaho; L. D. Anderson, of the United States Smelting, Refining & Mining Co.; and Anthony H. Godbe, president of the Prince Consolidated M. & S. Co. of Pioche, Nevada. The following day, Thomas Varley, superintendent of the local station of the Bureau of Mines, was the principal wit-

SURFACE PLANT AT THE VICTOR SHAFT, TONOPAH EXTENSION MINING CO.

in many years. The find was made by George Meuli, a pocket hunter from the Mother Lode country in California, after many efforts had been made by others to open ore in the same workings. The Spearhead has erected an electric hoist at the 112-ft. winze from the 910-ft. level and sinking has been resumed on a 5-ft. vein of quartz in the alaskite.

UTAH

SUIT FOR ACCOUNTING IS FILED AGAINST DIRECTORS OF THE MONTANA BINGHAM COMPANY.

SALT LAKE CITY.—Inquiry of the Federal Trade Commission into charges that the Minerals Separation Corporation, Minerals Separation North American Corporation, Beer-Sondheimer & Company, and other respondents, by an oppressive system of license agreements with mining companies for the use of flotation processes, have suppressed competition, opened at the Federal building in

ness. Mr. Varley's testimony was that he considered the license rate of the Minerals Separation Corporation and the other respondents had greatly curtailed the production of ore and its treatment by the flotation process, as the royalty charges were so excessive that many of the smaller companies and individuals could not afford to pay them. On the evening of July 14, Geo. L. Nye and Gilbert H. Montague, attorneys for the American Mining Congress, met at the Alta Club with a number of local mining men, explaining why the Congress was aiding the Trade Commission in its inquiry into the license methods of the Minerals Separation Company and its associates.

BINGHAM.—All preliminary preparations have been made for resumption of work at the old New England mine, now owned by the Utah-Boston Development Co. It is stated that the main working-shaft will be extended from the 300 to the 800-ft. level.

The Utah Apex Mining Co. is now employing 285 men at its mine and mill. V. S. Rood, general manager, re-

ports that the company is getting good results from the contract work in some of the large orebodies. In this work, the men are paid for the work they accomplish; the company furnishing all necessary materials, power, and powder.

It is reported that the main workings of the Montana Bingham property are to be connected with the Mascot tunnel of the Ohio Copper Co., for the purpose of facilitating transportation. Recent shipments from the Montana Bingham have ranged from 6 to 16% copper, 2 to 6 oz. silver, and \$1.50 to \$4 in gold per ton. Suit for an accounting of the affairs of this company was filed on July 14 by several of the stockholders against the directors and others. The complaint charges that the company's funds have been and are now being squandered in excessive salaries and bonuses; that the directors of the company secured control for the purpose of handling the funds for their own benefit. The complaint further charges that the defendants agreed to purchase 500,000 shares of the treasury stock of the company at a stipulated price of 50c. per share, on which consideration they were elected to the directorate. It is stated that not more than 265,000 shares of the stock has been so purchased. It is also alleged that C. G. Ballentyne was elected president and general manager for the company at a salary of \$105,000 for five years and that he was given a bonus of \$10,000 to come here from Honolulu to take charge of the property.

TOOELE COUNTY.—Ore-hauling has been resumed from the old Sharp mine, located about ten miles from Benmore, and about twenty miles from the Salt Lake Route. This mine was a heavy shipper some years ago, but in recent years only a small amount of ore has been mined. During the past winter operations were conducted in a limited way, and the ore extracted was piled until such time as the roads would permit of hauling it to the railway. The ore is rich in lead and silver. In the same section of the county, Alex Caldwell is developing a number of claims, in which there is reported to be a good showing. No ore has as yet been shipped but it is hoped to commence stoping later.

EUREKA.—John Manson, manager of the North Standard property, has been spending considerable time here of late. The shaft is below the 600-ft. level and sinking will be continued until the 1000-ft. level is reached if the showing warrants. A meeting of the stockholders of this company has been called for August 2, at which time a financial report, covering operations of the company to date, will be submitted. Recently there has been considerable opposition to the present management, and a lively time is expected at the meeting.

The Eureka pumping plant of the Grand Central Mining Co. was recently dismantled and the equipment moved to Mammoth, where it will be re-erected. Instead of getting its water from the wells at Eureka, the Grand Central is now being supplied by water from the springs near Diamond; this latter supply, running by gravity to Mammoth, is then pumped to the mine, the lift being considerably less than required at the Eureka wells. The

Grand Central is mining on all levels between the 540 and the 2100 at present.

PARK CITY.—During the week ending July 10, the Keystone Mining Company made its initial shipment. The Ontario Silver company is also shipping again, following a shut-down due to compressor trouble. The total shipments from the camp for the week were 2065 tons, as against 1807 tons for the previous week. The Ontario shipped 663 tons; the Silver King Coalition, 413 tons; the Judge M. & S., 534 tons; the Daly-West, 235 tons; the Naildriver, 165 tons; and the Keystone, 55 tons. The Park-Utah property is making arrangements to produce. Development work at this property is being done through the Ontario drain-tunnel, and the ore will be conveyed to the station on the 1500-ft. level of the Ontario, then raised to the 600-ft. level, and transferred to the loading station for marketing. For more than 450 ft. a vein of first-class ore has been followed, ranging from 10 in. to 4 ft. in width. No stoping has yet been done, owing to shortage of men, and the ore that is accumulating in the bins came from development work. A force of men has been employed for some time enlarging the station on the 1500-ft. level of the Ontario, installing additional track-age facilities.

BRITISH COLUMBIA

MANY CLAIMS HAVE REVERTED TO THE GOVERNMENT.

TRAIL.—The ore received at the Consolidated company's smelter during the last nine days of June amounted to 8755 tons, bringing the total for the half year up to 147,389 tons, of which only 3705 was in the form of concentrate. The first week of the new half year started well, 9036 tons of ore being received, of which 7231 tons came from the Consolidated company's own mines. The other shippers were: Bluebell, Riondel, 138 tons; Crescent, Greenwood, 2 tons; Emerald, Salmo, 47 tons; Electric Point, Washington, 133 tons; Florence, Princess creek, 35 tons; Josie, Rossland, 172 tons; Monarch, Field, 31 tons; Mandy, Le Pas, Manitoba, 1006 tons; North Star, Kimberley, 216 tons; and Sally, Beaverdell, 42 tons.

The Consolidated M. & S. Co. and 52 farmers have entered into an agreement to arbitrate claims for crop-damage to the farms supposedly due to smelter fume, and Judge Forin has been appointed arbitrator. Both parties to the pact have agreed that his decision shall be final. Under the agreement, the arbitrator has the power of awarding damages and also granting the smelting company a 'smoke easement' over the property and setting the value thereof. Should the arbitrator find that the damage from fume is so great that it is impossible to raise crops on any farm, he may decree that the smelting company shall purchase the property at a price he may set. Judge Forin is making a tour of the various claimants' farms and is accompanied by P. J. O'Gara, superintendent of the American Smelting & Refining Co.'s experimental farms of Salt Lake City, M. S. Middleton, formerly provincial horticulturist, who are acting for the company, W. J. Elmendorf, of Seattle, and W. H. Sleeman, of Annable, who are acting for the claimants, and

S. G. Blaylock, general manager for the company. Each claimant accompanies the party over his own property and points out damage that he believes to have been done by smelter fume.

SANDON.—Prospectors are active at this camp. Celano Polich is mining some good-looking ore from his claim and will ship a car of it to Trail this month. A tunnel is being driven in the Argo Fraction, better known as the Dutch Jake property. M. Byrnes is awaiting a run of water to clean up his placer claim on Carpenters creek. Spokane parties have bonded a number of properties at Zintcon and will start development at once. Gus Foundry has struck some good milling ore on the Majestic group. J. P. Wilson has a good showing on the Hope group. George Dean has struck a new vein on the Cinderella group. The Silver Card Mining Co. has let a

which have reverted to the Crown because of non-payment of taxes and now are subject to lease under the terms of the Taxation Act, have been completed. This publication is of surprising size, containing more than 30 pages. Every district of British Columbia figures in the tables it contains. As would be expected the sections best known to miners, because they have been longest prospected and are yielding the bulk of the mineral for which the Province is responsible, have contributed to the Crown the greatest number of delinquent mineral claims. The Rossland district has provided somewhat over 800 such properties, all of which, as stated, may be leased after compliance with the statutory formalities, the particulars of which will be furnished on application to the Assessor. The Slocan district, also, is well represented with about 300 such claims advertised for lease. Nelson has about

DALY-JUDGE MINE, PARK CITY, UTAH

contract for 200 ft. of driving. Some good ore is being taken from the old Payne mine.

AINSWORTH.—The New Canadian Metal Co. is unwatering levels 'B', 'C', 'D', and 'E' at the Blue Bell mine. These levels have been under water for two years, but the mine has been shipping steadily from the other workings. At the present time 45 men are employed at the mine, but this force will be increased considerably as soon as these levels are free from water and in condition for mining. The Nelson Iron Works built a special pump to unwater the mine.

STEWART.—During the winter the Premier mine shipped over 1500 tons of ore assaying about \$275 per ton. But for labor troubles, which persisted during the greater part of the season, a much larger quantity would have been shipped. Besides the shipping-ore, a large amount of milling-ore was mined, and this has been placed on a dump, awaiting the completion of the new 100-ton concentrator, which, it is expected, will be started early in August. Considerable development work and diamond-drilling have been done, and the mine is reported to be in splendid condition.

VICTORIA.—Lists of Crown-granted mineral claims,

328; Fort Steele about 90; Kettle River, 170. Many of these properties have not been sufficiently developed to conclusively prove their merit and probably will be further explored.

ALICE ARM.—J. A. McLennan, of Vancouver, B. C., president of a company organized to develop certain mining property in this district, on his return from the North stated that work on the Royal group, adjacent to the Dolly Varden, was giving satisfactory results. He asserts that the vein of the latter mine has been found on the Royal group, that it has been traced for 400 ft., and that a tunnel has been started on the 600-ft. level where the vein is well defined. There still is snow in the gulches but the season may be said to have opened. Every train leaving Alice Arm is well filled with prospectors bound for different parts of the interior.

SILVERTON.—Louis H. Biggar, a flotation engineer of Montreal, claims to have developed a process for the treatment by preferential flotation of the silver-lead-zinc ore of the Standard mine. He now is engaged in the construction of a six-cell plant, which will be ready for operation soon. The process will be used first in the treatment of a 5000-ton slime-dump averaging 11 oz. silver,

3% lead, and 7% zinc, which was accumulated before the adoption of flotation at the Standard. As this material averages 50% through 200 mesh the only way the silver and lead can be separated from the zinc is by a process of preferential or selective flotation.

ONTARIO

M'INTYRE COMPANY MAKES NEW HIGH RECORD OF PRODUCTION.

PORCUPINE.—Construction having been some time completed, the gold mines of this camp have settled down into a groove of steady production with comparatively few changes to report. The Hollinger Consolidated is treating about 1700 tons of ore daily, and no marked increase in this rate is anticipated for some time. Costs remain comparatively high, a recent increase having been made in the price of high-grade cyanide. The fiscal year of the McIntyre ended June 30 and forecast of the financial report indicates an income approximating \$2,000,000 with net profits of over \$1,000,000, constituting a new high record. Diamond-drilling at the Porcupine Crown has cut, on the 1100-ft. level, either a new vein or a faulted section of the orebody from which production so far has been obtained. The new discovery shows about five feet of quartz of similar characteristics to the main vein. Encouraging surface showings have been found at the Carveth property in Thomas township and the veins will be explored at depth by diamond-drilling before sinking is undertaken.

KIRKLAND LAKE.—The Teck Hughes is being operated to about two-thirds capacity with a force of 70 men, treating 2400 tons of ore per month. Underground work is mainly confined to the 400-ft. and upper levels, the ore at the deeper workings not being drawn upon. An important feature is the reduction of costs to approximately \$6 per ton. Similar economies have been effected at the Kirkland Lake where the average of operating costs has been reduced to below \$7 per ton. The physical condition of the mine is being rapidly improved. A raise has been made on a comparatively narrow orebody from the 200. to the 400-ft. level, and subsequent lateral work shows that the main orebody, 40 ft. wide in places, parallels this work at a distance of a few feet. The main vein of the Bidgood has been cut at the 200-ft. level where it has a width of about 15 ft. as compared with 12 ft. at the 100-ft. level. The shaft is being continued to a depth of 300 feet.

WEST SHINING TREE.—The Wasapika Consolidated announces that it is about to offer for sale 2,000,000 treasury shares of the par value of \$1 at 10 cents per share "in view of the speculative nature of the enterprise". The company is capitalized at \$6,000,000, \$1,000,000 in shares of the former company having been exchanged on a basis of three shares in the new company for one in the old. A further \$1,000,000 of shares were issued to finance the purchase of leases on three new claims lying to the north of the original Wasapika property and 2,000,000 shares were retained in the treasury. By the sale of these

it is expected to raise \$50,000 necessary for the installation of a mill capable of treating a minimum of 50 tons of ore per day.

FRONTENAC COUNTY.—The feldspar mining industry, the centre of which is at Tichborne, Frontenac county, in eastern Ontario, has increased considerably lately. Many new deposits of this mineral have been discovered and large shipments are being made to the United States. The Frontenac feldspar is regarded as superior in quality to that so far developed in other localities.

COBALT.—Increased activity is noted in the silver-mining areas of Northern Ontario, the field being again broadened by the success being obtained at Gowganda as well as South Lorrain. Prospectors are pointing to this as support to their earlier predictions that just as soon as interest became de-centralized and turned to the outlying fields, the likelihood of new producing mines would be strong.

Official advice from J. McIntosh Bell, who is in charge of the operation, confirms recent reports that success was being met in the development of the Keeley mine in South Lorrain. It is announced that silver ore to the width of three feet and averaging from 40 to 90 oz. silver to the ton has been found. This vein has been opened at the 230-ft. level as well as at a depth of 300 ft. While some of the richer shoots are yielding a fair amount of high-grade ready for shipment, the main output will be milling ore, the company now having an 80-ton mill in course of construction, which will be ready for operation by late summer or early fall. A shipment of between 10 and 11 tons of high-grade ore was made from the Castle property at Gowganda during the second week of July. The consignment was estimated to contain about \$15,000. On the recently opened Colonial mine, at Cobalt, a rich shoot of ore has been found, and the indications are that this property will take its place among the regular shippers. The Colonial lies adjacent to the O'Brien, having similar geologic conditions and a number of promising veins already opened.

Work has been curtailed on the Walsh mines, at Gowganda, it having been decided to remove the plant to an island near the north side of the property where it is planned to sink a shaft and explore that part of the property lying beneath the lake. The mill on the Reeves-Dobie mine is being operated 20 hours daily. About 25 tons of ore per day is being handled. Plans are being made to enlarge the plant so as to treat about 50 tons. In June, the Nipissing mine produced \$200,449. This compares with \$335,597 during the previous month. For the first half of 1920, the Nipissing output is valued at \$2,037,567, or at the rate of more than \$4,000,000 yearly, as compared with \$3,553,958 during 1919. Net profits for 1919 amounted to \$2,717,312, from which fact it is estimated that 1920 profits will be still higher owing to the indicated increase in output of about \$500,000. In addition to paying regular quarterly dividends of 5%, amounting to \$1,200,000 annually, the company is expected to make annual capital reductions of \$1,200,000, this being equal to \$1 on each issued share.

THE MINING SUMMARY

CALIFORNIA

Downieville.—The greatest gold discovery for many years in this section has been announced by the Gold Exploration Co., operating the Comet mine in Jim Crowe canyon. The orebody is said to be 30 to 50 ft. wide and has been proved for a length of 200 ft. with no limit yet reached. Officials state that shoots of bonanza ore accompany that of mill-grade, and that a wide face of high-grade quartz has been exposed. Plans are being made to replace the present mill with a larger and more efficient plant and to carry forward mining operations on a larger scale.

Plumas County.—The freight rate on ore shipped from points in Plumas county to Wabuska, Nevada, a distance of 180 miles, now is \$10.50 per ton, while the rate from the same points to Garfield, Utah, a distance of 680 miles, is \$9.70. Several months ago the Interstate Commerce Commission granted reduced rates after a hearing in San Francisco, but objections were made by the Western Pacific company and the reduced rate was suspended. The Mason Valley Mines Co. is petitioning for a return to a lower rate, which will mean the resumption of operations at the smelter at Wabuska. The company also will begin immediately to develop and produce ore from properties it controls in Plumas county, it is said. Arguments are to be heard by an examiner of the Commission at Reno on July 26.

Sierra County.—The Twenty-One Mining Co. has sold all its mining property to the Sixteen-to-One Mining Co. The deal marks the ending of bitter litigation, in which the Sixteen-to-One secured a judgment for \$60,000 for ore extracted from its ground. The \$60,000 judgment is a part of the purchase price, the rest being cash. The Twenty-One holdings consist of four valuable quartz mining claims, together with a ten-stamp mill and other surface improvements, and the Sixteen-to-One intends to operate through the Twenty-One tunnel, as well as through its own workings.

MISSOURI

Joplin.—Fire destroyed the roof, interior woodwork, and all of the bags at the bag-house of the zinc-oxide plant of the Metals Extraction Corporation at the State-line west of here on July 9, causing a loss of \$10,000, which is covered by insurance. The fire started by sparks falling on a small frame building near the bag-house. The Galena fire-department arrived too late to prevent complete destruction of the interior bag-rooms. The walls and floors are of concrete and were not damaged. A force of men started immediately clearing away the debris and will re-build the interior of the house as quickly as possible. A metal roof will be put on the building to make it completely fireproof. The plant had been operating for several weeks in the manufacture of zinc oxide by a modified process. Two furnaces have been working, turning out from 7000 to 10,000 lb. of oxide per day, and other furnaces will be added soon to bring the output up to 70,000 to 80,000 pounds.

NEVADA

Contact.—Stockholders of the Seattle-Contact Copper Co. have received their first dividend checks. The company is shipping large quantities of high-grade ore by way of Rogerson. At a recent meeting of the stockholders of the Javan Mines Co. a report was rendered by the general man-

ager announcing a recent discovery of high-grade ore. Persons familiar with conditions in the company's workings predict one of the biggest producing properties in the Contact district.

Eureka.—More ore of shipping grade is now exposed in the Eureka-Croesus mine than ever before, and returns from the smelter on shipments sent out prove that material assaying \$70 per ton is being mined from good-sized bodies in several places on the 400-ft. level. The company has been under heavy expense for the past two years in equipping the surface plants, purchasing freighting outfits, and sinking and drifting to reach and prove orebodies that were in the beginning believed, and later proved, to exist in the limestone below the old workings. The Eureka-Climax is building a chute from the portal of the Mabel L. tunnel to a bin on the road about 40 ft. below, for storing the ore. The tunnel is being pushed through the Dead Broke claim. The Eureka-Prince is drifting on the 150-ft. level, connections for air having been made with a winze above. The ore on this level is about three feet wide, mostly of good shipping grade. The gold content is high in portions of it, one sample of those assayed this week containing 5.2 oz., together with 248 oz. of silver, per ton. The ore is a brownish-black loosely-cemented lead carbonate, and while this assay cannot be considered representative of the orebody on this level, it shows that ore of exceptional value is being found. The Eureka-Holly last month sent 300 tons of ore to the Utah smelters, the largest amount ever sent out from the mine in 30 days. All of this ore runs \$75 per ton or more, and the same grade is being mined and hoisted daily, with the main orebody still averaging about 10 ft. wide. The Ruby Hill is shipping ore as fast as cars are available, and rapidly completing pumping preparations on the 900-ft. level.

OREGON

Gold Hill.—The War Eagle Mining Co. has let a contract to W. H. Stickel of Gold Hill to burn 200,000 brick at the mine, 12 miles north of Gold Hill, to be used in the construction of a 30-ton Scott mercury-furnace. The property, consisting of 36 claims, known as the Utah group of mercury mines, was purchased by Salt Lake City men in 1915 from the original locators and later sold to the Seattle men who developed the property. The mine is equipped with two 12-pipe mercury furnaces with 10-ton capacity and has been a steady producer since 1915. The present equipment has been used only on high-grade ore, running better than 17%, but with the completion of the Scott furnace ore running as low as 2% can be reduced at a profit, with mercury selling at present prices of from \$80 to \$90 per flask of 75 pounds.

YUKON TERRITORY

Mayo.—There has been a stampede to a new strike that has been made near Mount Hinton, on the opposite side of Lightning creek to Keno hill and about five miles from it. Under the belief that it is an extension of the Keno Hill deposits, it is stated that claims are being staked all the way between the two deposits. Ore running from \$1000 to \$2000 per ton is being taken from some of the Keno Hill prospects. In one instance a five-foot vein has been stripped for more than 200 ft., and is said to carry more than 1000 oz. in silver.

ECONOMICS AND GOLD MINING ON THE RAND

At the annual meeting of the Crown Mines company at Johannesburg, on June 17, the chairman, Mr. Samuel Evans, said that the net premium on gold produced this year from January to May totaled £292,000, which was equal to 21s. 1d. per ounce, or 7s. less than the increase in costs per ounce since 1913.

The working costs were now considerably higher than they had ever been, owing to increases in wages to white labor, stores, and other costs. White wages show an increase this year of 69% on the 1915 figure, when 103,000 more tons were milled. The average monthly earnings of the European workers have gone up from £24 6s. 10d. per month to £40 1s. 7d., an increase of 64.6%. Stores show an increase of 33%, and other costs 36%, as compared with 1915. Reverting to the working costs, Mr. Evans expressed the view that the increases were due mainly to the replacement of gold by paper for currency purposes in South Africa and elsewhere. The index numbers showed that the purchasing power of gold in England was now rather less than half of what it was in 1914. It had not diminished in the same ratio in South Africa, as they started at a different level. Taking everything into consideration, it was not an exaggeration to conclude that had the commodity value of gold remained stable since 1896 the mines of the Rand would be working today at a cost averaging something well under 12s. per ton, compared with 22s. 9d. last year and a much higher figure now.

Notwithstanding the example of England, where an effort was being made to keep paper money within bounds, the banks in South Africa had been issuing paper money at an accelerating pace. On the outbreak of the War the banks had £2,150,000 in circulation in South Africa. During the War they issued an additional £4,000,000 worth of notes, and since the Armistice they had added £3,500,000 to the paper circulation of South Africa. He was afraid that the dangerous character of the action of the banks was not appreciated by the Government and Parliament. Instead of taking prompt and effective steps to make an end as quickly as is safely possible to the senseless creation of artificial buying power, it appeared that serious consideration was being given to measures which, if adopted, would almost certainly have the effect of further disturbing the currency and plunging South Africa deeper into the paper-money bog. It hardly seemed a sane policy for the Parliament of the largest gold-producing country in the world to enact laws encouraging and facilitating the supersession of gold by paper.

If the majority of the mines on the Rand were to be kept working, not only must the upward movement of prices be arrested, but there must be a reduction in prices, and that could only be accomplished by limiting and diminishing the supply of paper money. He spoke strongly, as he felt there was a real danger that in order to give temporary relief to the banks and the wool and other interests Parliament might adopt a course which was bound to terminate disastrously, however promising it might appear now. The afflictions caused by the excessive issues of paper money could only be made worse by further issues. In spite of the menacing character of the immediate outlook in South Africa, he was disposed to take a more optimistic view of the gold-mining industry than was usually held. Many people, even among the leading economists, believed that paper money had come to stay, and that the commodity value of gold would remain at a permanently lower level than in 1914. The experience of France under Napoleon justified the conclusion that the countries which first completely abandoned paper money and returned to specie payments would be the first to recover their prosperity, and that their good fortune would force the others to do likewise. He looked forward to a similar outcome at the present time.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

D. D. Moffat is at Los Angeles.

W. J. Loring is in Washington, D. C.

C. W. Purington writes from Kobe, Japan.

James S. Douglas was in the Ray district last week.

Bond Coleman has moved from Zacatecas to Mexico City.

E. D. Bullard Sr. arrived last week from the East, where he has been for two months.

Arthur Mort passed through San Francisco on his way from Beluchistan to London.

Hugh B. Lowden, of the Colorado Iron Works, Denver, was in San Francisco this week.

Harold A. Linke, mining engineer of Salt Lake City, is examining lead-silver properties near Hailey, Idaho.

Frederic R. Weekes has returned to New York from a six weeks professional trip to Montana and California.

Hilding Magnusson, mining engineer for a large steel company in Sweden, spent a week in Utah recently.

W. S. Boyd, manager for the Ray Consolidated Copper Co., was in San Francisco and Salt Lake City recently.

Warren D. Smith sails on the 'Shino Maru' for the Philippines, where he is Active Chief of the Division of Mines.

J. Walter Beam, superintendent of the Benguet gold mine near Manila, P. I., is visiting at his old home in Salt Lake City.

Henry W. D. Hayden, recently acting superintendent of the Suan mill, at Holkol, Korea, has returned to San Francisco.

H. C. Goodrich, chief engineer for the Utah Copper Co., and George C. Earl, assistant mine engineer, are in San Francisco.

J. B. McIntosh, of Salt Lake City, has gone to Pachuca, Mexico, to accept a position with the United States Smelting, Refining & Mining Co.

Guy C. Riddell, formerly adviser to the U. S. Tariff Commission, is now consulting engineer to the Wah Chang Trading Corporation in New York.

Howard A. Eavenson has resigned as chief engineer to the United States Coal & Coke Co., to open an office as consulting mining engineer at Pittsburgh.

E. A. Holbrook, superintendent in charge of the Pittsburgh experiment station of the Bureau of Mines, has been appointed Assistant Director of the Bureau.

H. S. Weigall has been demobilized with the rank of Major and has returned from England to Korea as assistant general manager for the Seoul Mining Company.

Lester S. Grant, Professor of Mining in the Colorado School of Mines, has motored from Golden to San Francisco, visiting various mining districts on the way.

Walter A. Scott, formerly counsel for the Butte & Superior Mining Co. and other defendants against Minerals Separation, now living at Los Angeles, was in San Francisco this week.

Rudolf Gahl has been retained by the Cerro de Pasco Copper Corporation as consulting metallurgist in connection with its milling projects and sailed for Peru from New York on June 30.

Jackson A. Pearce, who is now with the Compagnie du Boleo, in Baja California, was in San Francisco recently and testified before the Federal Trade Commission in the Minerals Separation affair.

A. G. Burritt, geologist of Salt Lake City, has recently returned from northern Mohave county, Arizona, near St. George, Utah, where he has examined promising oil lands. He is now at DeBeque, Colorado, for a few days.

METAL PRICES

Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

July 19.—Copper is steady and quiet. Lead is inactive but strong. Zinc is dull but firm.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

INTEREST RATES AND DEFLATION

The subject of interest rates is one that is of vital importance, not only to bankers but to every business man and to the community at large. The bank's profits depend largely upon the return received for the use of its money and the merchant's welfare and success depend to a great extent upon his ability to borrow from the banks at as low a rate as possible, according to the Chemical National Bank of New York. Recently, and in fact during most of this year, the papers and financial magazines have been setting forth the advantages and disadvantages of inflation and ruminating upon the apparently ever-increasing rates for the use of money. To the uninitiated or to those who have not had the opportunity to study the subject, it may seem almost unbelievable that interest-rates could go higher than 6%, which is generally thought to be the maximum. These persons fail to take into account the fact that money is a commodity, the same as wool, meat, or anything else, and its value depends upon the old law of supply and demand. It is, therefore, no more possible to set a maximum figure for which money can be loaned, and have interest rates remain at that figure, than it has been to set a maximum price for sugar, which recently, due to an actual scarcity, has reached a price never before equaled since the Civil War. During the recent war the Government had the power to fix the prices of certain commodities, but this was merely a temporary measure and was not based upon the law of supply and demand. The Federal Reserve banks, through a policy of higher re-discount rates, have recently inaugurated a period of deflation which is well under way. Had the era of inflation been allowed to make greater headway, the result might have been a panic, but, an orderly re-adjustment is now in progress.

One of the principal reasons for putting an end to inflation was to bring about lower prices. There is no need of explaining that commodities of all kinds have recently reached figures quite out of proportion to the average person's pocketbook. One way of bringing about lower prices would have been to increase production, when prices would naturally fall. But, with the laboring class demanding shorter hours and no one willing to work on our farms, greater production has not been possible, at least for the present. The other method of lowering prices, at least to some extent, is that of decreasing consumption. A combination of both methods would probably be the most desirable, but since this could not be had, it is evident that the latter method was the one to be followed.

The result of the Federal Reserve Board's policy of deflation is already apparent and, while the process may be unpleasant for the time being, there is no doubt but what the outcome will be of benefit to all. As long as the merchant uses his own money for speculative purposes there is no great objection, but when he speculates with his bank's money, resulting in generally increased prices for commodities, there is no question but what the wrong policy is being pursued. Money today is scarce, but there is plenty for legitimate business needs.

While the Federal Reserve banks probably took the first actual step in the process of deflation, the situation has been more or less affected by the outflow railroad strike, the results of which have recently become more apparent, with deliveries of merchandise held up at all points. There is a vast amount of 'frozen credit' which cannot be released until there is a free movement of goods. Merchants and manufacturers awaiting delivery of goods have, therefore, been obliged to borrow very heavily from the banks. Until there can be prompt liquidation of such credits, the increase in the discount rates adopted by the Federal Reserve banks can be of little effect except to check additional borrowings.

Another instance of the scarcity of money is the fact that the Treasury of the United States, when seeking \$400,000,000 a few weeks ago, was obliged to pay the highest interest charge in half a century. The new treasury certificates bear 5 1/2% and 6% interest and the Secretary, with the combined wisdom of the other treasury officials, evidently believed that high rates at least will prevail for a year. The ultimate aim of all remedies for inflation is to reduce the high cost of living, and every effort toward that end should be made, but just as long as there is an actual shortage of goods, and labor insists on a short day of inefficient work, we cannot expect permanent results.

MONEY AND EXCHANGE

Foreign quotations on July 20 are as follows:

Sterling, dollars:	Cable	3.83
	Demand	3.82 1/2
Francs, cents:	Cable	8.23
	Demand	8.20
Lire, cents:	Demand	5.76
Marks, cents	Demand	2.60

Eastern Metal Market

New York, July 14.

There is a better tone to all the markets but business is not heavy. Prices are firm to higher.

Inquiry for copper is reported as considerably improved and the tone of the market is stronger.

The market for tin is quiet with the light transactions confined to dealers. Spot Straits is nominal.

Conditions in the lead market are but slightly changed.

The tone of the zinc market is strong with the price tendency upward.

The antimony market is quiet and unchanged.

IRON AND STEEL

Against the protests of iron and steel producers the Interstate Commerce Commission has extended for 30 days from July 21 its order confining the use of open-top cars to coal. It remains to be seen how far the shut-downs, that steel companies said were inevitable, will go. Some relief is given by exempting from the order all flat-bottom gondola cars or cars which on June 19 had been definitely taken from coal-carrying service, this being one modification asked by iron and steel interests.

So far as the merchant pig-iron trade is concerned, the soaring of fuel prices has caused as much concern in the past week as the car troubles to which high prices for fuel is chiefly laid. There is an urgent call from some quarters for a return to the Government control of fuel that was given up on April 1, producers of pig-iron viewing with dismay sales of prompt coke at \$19 this week, while bituminous coal has brought from \$10 to \$12 at the mines.

In the Pittsburgh district more steel-making and finishing capacity has been idle or has run intermittently this week than in the preceding week. Two large steel-pipe works which closed down July 3 have not yet resumed.

Soaring fuel prices are playing havoc with cost-sheets. In the case of a large steel interest the advance in June was between \$1.50 and \$2 per ton.

Export business keeps up on a good scale. Some irregularities in prices have resulted from the re-sale of material bought from Japan, but the tonnages are not significant. A 5000-ton ship-plate order for export was placed at 3.75c., Pittsburgh.

COPPER

The tone of the market is reported as considerably improved. There is a good deal more interest from consumers, although this has not yet developed into business. Sales, however, both for domestic and foreign account, continue satisfactory and prices are firm. It is reported that offerings in the outside market have been pretty well absorbed and that prices there are firmer. An interesting statement is to the effect that consumption of copper at present is "enormous, running into 60,000 net tons per month". It is certain that this is in excess of production at present. Prices of the leading producers continue firm at 19c., New York, for both Lake and electrolytic copper at which sales have been made for prompt delivery and into the third quarter. In some cases transactions for delivery in October are also made at correspondingly higher prices. There are offerings in the outside market at 18.75c., New York, but purchases can be made at 18.50c.

TIN

This market has been lifeless and quiet the last week. Consumers continue to hold aloof. Some dealers could have been buyers at prices somewhat below the market but sellers have been indifferent. As a consequence total sales have been light and spot Straits continues in light supply and prices are nominal. On the New York Metal Exchange, total

sales last week were around 200 tons, nearly all future shipment, at prices ranging from 47c. to 50c., depending on the position. Late last Friday one dealer reported an active inquiry for 300 to 400 tons, but aside from this there was little of interest. The same conditions have prevailed thus far this week. Spot Straits yesterday was quoted at 50.25c., New York, but largely nominal. In London yesterday spot Straits was quoted at £281 per ton, against £259 a week ago. Spot standard tin was quoted yesterday at £260, the spread between the two being due to the scarcity of Straits tin. Arrivals thus far this month have been 1730 tons, with 5430 tons reported afloat.

LEAD

Basic conditions in this market as discussed a week ago are but little changed. There is some demand for prompt metal, but the scarcity makes it difficult to obtain. Some has been sold, however, for quick shipment at the equivalent of 8.65c., New York, and there was also a sale of early August shipment at the equivalent of 8.45c., New York, but the total in both cases was not large. Without doubt more could have been sold had there been sellers who possessed the metal. The leading interest is apparently not selling, and hence its quotation of 7.75c., St. Louis, or 8c., New York, is nominal. In the outside market quotations may be conservatively put at 8.15c., St. Louis, or 8.40c., New York, for early delivery.

ZINC

There has been little change in this market during the week. Demand continues moderate and prices firm, with the tendency upward. Prime Western for third quarter delivery is quoted at 7.85c., St. Louis, or 8.25c., New York, while for July 7.90c. to 7.95c., St. Louis, has been realized. The fact that production is curtailed, as noted a week ago, and that producers are fairly well sold for July, makes for a technically firm, to strong, market. Producers are at least not inclined to quote beyond July.

ALUMINUM

Demand is light and quotations are unchanged at 33c., New York, for wholesale lots of virgin metal for early delivery by the leading producers, and at 31.50c. by outside sellers. The former quotation is nominal.

ANTIMONY

The market is quiet and unchanged at 7.50c. to 7.75c., New York, duty paid, for wholesale lots for early delivery.

ORES

Tungsten: The market is exceedingly quiet and devoid of features. Prices are nominal at \$6.50 up per unit in 60% concentrate, depending on the grade of ore.

Ferro-tungsten is quoted at 85c. to \$1.05 per pound of contained tungsten.

Molybdenum: Conditions are unchanged and prices are nominal at 65c. to 75c. per pound of MoS₂ in regular concentrate.

Manganese: The market is quiet with prices firm at 70c. to 75c. per unit for high-grade ore. The largest consuming interest has contracted for about 20,000 tons per month of Indian ore for delivery in the next year.

Manganese Alloys: Production of ferro-manganese in June, according to the blast-furnace reports of 'The Iron Age', was 26,265 gross tons, which is larger than for any other month this year or in 1919. Prices continue firm at \$200 per ton, delivered, for the last half and \$225 for spot. Some British alloy is available at \$195, seaboard, for shipment from August on. Demand is light and sales are confined to small lots for early shipment. Spiegeleisen is quiet and firm at \$75, furnace, for prompt and early delivery.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

COPPER-CONVERTERS AT CLARKDALE, ARIZONA

The accompanying illustration shows the copper converters at the smelter of the United Verde company at Clarkdale, Arizona. They are made by the Allis-Chalmers Manufacturing Co., being the standard vertical or 'Great Falls' type of machine.

In this type of converter the shell is made of heavy steel plates, with two cast-steel trunnions riveted on, one of which is fitted with a removable cast-steel riding-ring and the other with a cast-steel removable riding and gear-ring. Both trunnions are rough-machined on the inside to give a per-

fect bearing on the steel shell, in exact alignment with the centre line of the shell, carrying rings and driving gear. Where the tuyeres enter the shell it is reinforced by a heavy steel plate. The hood or top half of the shell is made in one piece of cast steel and is bolted to a heavy cast-steel reinforcing angle, which is riveted to the upper part of shell. Lifting lugs are riveted to the shell and cast integral with the hood. One of the trunnions is provided with an opening for the passage of the blast, and arranged to connect with a cast-steel or cast-iron wind-box; the wind-box being held by a bracket secured to the shell. A sheet steel shield is secured to the shell, to prevent accumulation of slag on top of wind-box. The shell is provided with individual tuyeres and ball-valves both of which can be removed easily. The tuyere-bodies are made of cast-iron with covers of cast-steel. The ball-valve is held in a suitable casing, cast integral with the cover of each tuyere, from which it can be removed or replaced by taking off the tuyere cover. The tuyere-bodies are arranged for fastening to the bottom of the wind-box

with brass sleeves and coupling nuts, forming an air-tight connection. The tuyeres are made of extra heavy pipe, of proper length to extend into the shell and through the lining. At a point where the tuyeres enter the shell, a flange or stuffing-box for each tuyere is attached to the shell and arranged for retaining a suitable packing around the tuyeres, so that the joint will be air-tight. The lower end of the tuyere bodies are attached to a steel bar, to keep the tuyeres in proper alignment. A flexible blast-connection is attached to the trunnion, which allows the shell to rotate and admits of any slight difference in alignment between the shell and the blast-pipe. For controlling the blast a lever-operated quick-opening gate valve is supplied. The stationary part of the blast-connection is supported by a standard having bolted connection on one end and a ball-support on the lower end, which fits into a spherical socket on a bracket attached to the roller frame. The converter-shell is supported on two stands, one placed at each end. These stands are of heavy deep-box section, strongly ribbed, having suitable bosses for foundation-bolts. The angle roller-bearings mounted on these stands are securely bolted to same, and are provided with large grease-pockets and cups for lubrication. The stand at the driving end has cast integral therewith an extension which forms the base for supporting the worm, worm-shaft, and bearings for same. There are four cast-steel supporting-rollers on which the shell is rotated. Two have plain faces, to permit lateral movement of the converter, due to expansion. The other two are flanged to suit the combined riding and gear ring. The supporting roller on the driving shaft is a combined carrying roller

Four 12-ft. 'Great Falls' Copper-Converters at the United Verde Smelter

and spur pinion, having the bottom of the gear between the teeth cast open, to avoid binding of the gear and pinion-teeth. The other flanged roller has two turned faces for the riding-ring and a recess into which the gear-teeth pass; the driving is done entirely from the shaft on which the worm-wheel is mounted. The supporting rollers are mounted on heavy forged-steel shafts. The converter-shell is tilted by means of a worm-wheel consisting of a cast-steel spider fitted with a removable bronze rim accurately machined. A forged-steel worm is provided which is accurately machined and mounted on a steel shaft which is coupled to the motor. This worm-shaft is fitted with a compression coupling by means of which it can be disconnected from the motor shaft, in order to allow of withdrawal of the worm and shaft from the casing. The worm-wheel is surrounded by an oil-tight sheet-steel housing, which is fitted to the inside of the worm-box. This housing consists of an upper and lower half and a removable cover on the outer side, giving access for inspection and repairs. The tilting mechanism is operated by

and spur pinion, having the bottom of the gear between the teeth cast open, to avoid binding of the gear and pinion-teeth. The other flanged roller has two turned faces for the riding-ring and a recess into which the gear-teeth pass; the driving is done entirely from the shaft on which the worm-wheel is mounted. The supporting rollers are mounted on heavy forged-steel shafts. The converter-shell is tilted by means of a worm-wheel consisting of a cast-steel spider fitted with a removable bronze rim accurately machined. A forged-steel worm is provided which is accurately machined and mounted on a steel shaft which is coupled to the motor. This worm-shaft is fitted with a compression coupling by means of which it can be disconnected from the motor shaft, in order to allow of withdrawal of the worm and shaft from the casing. The worm-wheel is surrounded by an oil-tight sheet-steel housing, which is fitted to the inside of the worm-box. This housing consists of an upper and lower half and a removable cover on the outer side, giving access for inspection and repairs. The tilting mechanism is operated by

either a direct or alternating-current, variable-speed, back-geared motor of the well-known Allis-Chalmers type, especially designed for this service.

For operating the motor, a reversible 'drum type' controller and 'grid type' resistance are provided. There is also provided a solenoid brake for automatically stopping the machine at any time when the current is shut off. The motor and solenoid brake are covered with a sheet-steel housing, provided with two sliding covers for inspection, which are easily removed. A storage-battery safety system, which automatically takes the control from the operator in case of failure of electric current, and rotates the converter to a 'safe' position, should the tuyeres be submerged when such a failure occurs, can be supplied with the converter.

NATIONAL AIR-COMPRESSORS

Air-compressors, in sizes from $\frac{1}{2}$ to 150 hp., are being manufactured in Los Angeles by the National Compressed Air Machinery Co. The compressors are constructed in two general types; the single-cylinder Class 'S' machine is for light work; the two-cylinder Class 'D', 'D2S', and 'DVL' are designed for those whose requirements are greater. The duplex types are made in a wide variety of sizes and for pressures of from 10 to 500 lb. per square inch. The leader in the duplex type is the Class 'D', two-cylinder, single-stage, single-acting, as illustrated in the accompanying cut.

Some of the features that distinguish this machine from other makes that look about the same are as follows: The main bearings are three in number, all adjustable by the removal of laminated shims, and any one removable with-

Class 'D' National Air-Compressor

out disturbing any other. Equally important these bearings are carried on heavy bridges cast in the main frame. The cross-head guide is free from stuffing-box troubles and the cylinder walls get no side-thrust wear. Lubrication is by splash only. There is not a lubricator, oil, or grease-cup on the compressor. The cylinder wall lubrication is controlled by the apron, on the piston, dipping into a groove kept filled with oil by the cross-head. Enough without too much is the answer to the cylinder-lubrication problem in this design. National arch-disc valves are used in all National air-compressors. They are guaranteed for two years against breakage in use. Inlet and outlet valves are interchangeable. They are a happy medium between the old, self-destructive poppet valves, and the host of frail, and in many cases complicated, so-called plate valves. While being efficient and silent, they stay tight and they 'stand the gaff'. There are no extra parts, such as buffers, stop-plates, guides, or washers. For each valve there is but one spring, one cap, and nothing else. Both the single and two-cylinder are furnished bare, or in complete assembled outfits, including

motor or engine drive, pressure-unloader, and electric, pneumatic, or other types of control, as best suits the user's conditions.

SIMPLE DEVICE FOR STRIPPING OUT INNER STRAND OF STEEL CABLE

An interesting salvaging operation was recently carried out successfully by the Spanish-American Iron Co., a subsidiary of the Bethlehem Steel Corporation, in Cuba. The inner strand of a three-inch steel cable which had been condemned and discarded because of worn and frayed outer strands was salvaged and the worn strands cut into six-foot lengths for the charging-box. Both the inner strand and the scrap were well worth saving, as the cable was a mile and a quarter long and the reclaimed strand ($1\frac{1}{2}$ in. diam.) was practically as good as new.

The problem involved was to cut away the six worn strands without damaging the valuable inner strand. This was accomplished by means of a simple but ingenious device constructed on the ground out of scrap material. Suitable lengths of iron pipe, of a size convenient to grip with the hand, were oxwelded into the rim of a small iron pulley in such manner as to resemble spokes of a wheel with the tire and fellos missings. A short section of sheet-iron pipe, slightly smaller in diameter than the pulley but larger than the shaft bore, was then welded to it in line with the bore by the use of four strips of strap iron.*

The strands of the cable were then pried apart for a few feet to admit of passing the inner strand through the hub and its extension, and the feeding of the outer strands through the six spaces between the spokes. With the strands so adjusted the device was revolved against the wind of the cable and advanced as the strands unwound, the inner strand being allowed to lie in a continuous length along the course of the work and the worn members being easily cut into the proper lengths with the oxy-acetylene torch. The length of the spokes gave the necessary leverage for operation of the device by hand. The cable, of course, remained stationary, the inner strand being coiled and the scrap collected after the work was completed. The job was done in jig-time, the oxy-acetylene flame snipping off the worn strands with almost chopping speed.

The use of the oxy-acetylene cutting, which was done with a portable Oxweld outfit, made simple and inexpensive an operation that would have been prohibitive by any other mechanical means, as it was equally out of the question to carry shears of sufficient power to the work or to convey the work to the shears. Thus the salvaging was accomplished with dispatch and economy, netting the owners of the cable a handsome profit on material that could not have been profitably reclaimed by any other process.

The Molybdenum Corporation of America, having the same executive and operative personnel as that of the Electric Reduction Co., announces that it has acquired as of July 1, 1920, the plant, equipment, and operations of the latter company at Washington, Pennsylvania, together with molybdenum mines in New Mexico. This company will continue to furnish ferro-tungsten, ferro-molybdenum, and other high-grade ferro-alloys, metals, and chemical products with no change in policy whatever. Having now direct control, from the crude ore to the finished material, the Molybdenum Corporation of America is in position to render exceptional service in supplying molybdenum products.

*The use of the pulley and pipe-extension was necessary only because a suitable length of pipe was not at hand. A single section of pipe of the right size to allow for welding in the spokes and long enough to keep the inner strand from curling would be much simpler and would answer the purpose equally as well.

EASTERN METAL MARKET	180
----------------------------	-----

Established May 24, 1860, as The Scientific Press; name changed October 10 of the same year to Mining and Scientific Press.
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 3514 Woolworth Bldg.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

THE METAL MASTER

WITH an Oxweld welding or cutting torch the welder of to-day is performing miracles.

Problems of production which a few years ago were considered unsolvable are simple now because of this modern Master of Metals.

Oxweld Research Engineers are constantly bringing to light new applications of oxwelding and cutting to industrial uses—keeping pace with the growth of American enterprise.

The story of the development of the oxy-acetylene process is the wonder-tale of modern industry. Everywhere it is lightening labor, improving products, saving time and money.

Oxweld Service Engineers in fifty important cities will gladly tell you how Oxweld can be applied in your plant to your advantage.

Write, wire or telephone to any of the addresses below for immediate attention.

OXWELD ACETYLENE COMPANY

WORLD'S LARGEST MAKER OF EQUIPMENT FOR
OXWELDING AND CUTTING METALS

T. A. RICKARD, Editor

RESUMPTION of trade with Russia will include the shipment of a product for which there is no demand in the United States, namely, Bolsheviks. The removal of commercial restrictions will render practicable the deportation of about a thousand 'Reds', from Russia, Esthonia, Finland, and other parts of what was formerly known as the Russian empire. It is stated that a number of these anarchists are out on bail, on account of the embargo against American ships entering Russian ports. That embargo is now lifted. We hope the departure of the undesirables will be expedited and that more care will be taken to prevent them or others like them from re-entering this country.

IN the course of expanding its bureaucratic organization at Washington, the American Mining Congress has decided "to create a tax division under the direction of a man who has given tax matters thorough and careful consideration, and who will be in a position to render assistance to both the Government and the tax-payer". One would think that among the 35,000 employees in the Treasury department there would be a man "who has given tax matters thorough and careful consideration", such consideration as would enable him to arrive at an intelligent decision in difficult cases. Either the Treasury department is ridiculously inefficient, despite its huge payroll, or else the Mining Congress is adding to its organization needlessly.

WILD-CATS wearing an engaging smile, like the proverbial Cheshire feline, are as numerous in Australia as in the United States. We have read recently a description of a remarkable mineral deposit at Miva, in Queensland, where an "unlimited" tonnage of ore assaying 73% iron has been uncovered. This ought to be enough for one story, but we are told by the irresponsible scribe that "oxide of iron and white and red lead of good quality have also been found in fair quantities, and gold, the assays yielding 15 dw. and 9 dw. respectively of the latter metal". Evidently all that is needed now is an oil-well in juxtaposition; then with one product the good people of Miva can paint things red and with the other they can whiten a reputation darkened by such divagations from the truth. We are reminded of the deposit of soapstone that was found in the sagebrush desert many years ago and was described as "natural

soap", useful for removing stains from the escutcheon of the State of Nevada, which at that time had become somewhat besmirched by the fiscal activities of Graham Rice and other peddlers of wild-cat scrip.

DANIEL GUGGENHEIM has 'called the turn', as they say, more than once, so we note with pleasure his statement, made just before sailing for Europe, that "there is absolutely nothing in the present situation to justify any pessimism". Presumably the cost of sugar or of gasoline does not worry Mr. Dan. as it does some of the rest of us. In regard to the metal markets, he says: "The clearing up of the foreign exchange situation and financial readjustment on the part of European countries will materially relieve present uncertainties. We are now marking time, but I wish to emphasize that there is nothing to justify any pessimism." He says it twice, so he must mean it. His opinion on such matters is usually well founded.

EIGHT editors are needed to prepare the weekly output of our contemporary at New York, so its editor-in-chief states in the latest issue to hand. We have three editors on our staff, one of whom, we regret to say, has been absent on sick leave for five months. The two salute the eight! The editor in New York explains that "the editorial which you find so punk or offensive is the work of the jail editor". We have noticed no editorials that were offensive; but as to the jail, we are reminded of the lady who showed her new maid a room and explained that it belonged to her son, "who is at Yale", she added. Whereupon the Swedish damsel replied that she also had a brother "in yail; he got to stay there 60 days". We hope the gentleman in New York, and probably from Columbia, will retain his dangerous post for more than 60 days and enjoy his sentences.

WE take pleasure in publishing a scholarly article, on the relation of science to industry, by Mr. A. W. Allen, who, just now, is in Chile. He makes a plea for scientific research as the handmaid of industrial development, and he does it in terms that will enlist the interest and sympathy of all thoughtful citizens. It is well occasionally to look beneath the surface of things and remind the community of its obligation to science, and of the need, if only on account of enlightened selfishness,

to foster the investigation of those basic principles, in chemistry and physics more particularly, upon which, for example, the progress of mining and metallurgy depend. Mr. Allen does that for us effectively, illustrating his argument by reference to the story of the cyanide process and the function of oxygen in precipitation. The recent disorganization of the Geological Surveys of both the United States and Canada by reason of the inadequate pay allowed to those engaged in an important phase of scientific research, is another illustration of a condition to which it is well to draw notice at this time.

THE La Rose Consolidated Mines Company has started legal proceedings to compel the Mining Corporation of Canada to compensate it for the old tailing from the La Rose ores treated in the Northern Customs Concentrator that is now being re-treated by the Mining Corporation. Tailings derived from ores from various mines were impounded without attempt at segregation in the bed of Cobalt lake. The defendant company in the present action is obtaining a profit from re-treating the old tailing with which is intermingled some from the La Rose ore. The plaintiff contends that it is still the owner of the residue from the first treatment and is entitled to a share in any profit that may be won. Without knowing exactly the particular circumstances under which the Mining Corporation acquired its interest in the tailing, we are unable to present its side of the controversy, but the search for an equitable basis for settlement offers an interesting problem.

NEW regulations covering the leasing of phosphate lands have been issued by the Secretary of the Interior under date of May 22, yet the local land-offices, we are informed, have as yet received no copy of them; meanwhile they have been authorized to accept applications for lease, but not to transmit them to Washington. This suggests a curious failure to connect. These new regulations specify a minimum royalty of 2% on the gross value of the output, but they fail to state the maximum royalty, or indeed to indicate at what figure the royalty will be fixed. Of the annual "investment" on the lease, meaning probably the money spent, not less than one-third must be expended in actual mine development, "and a like amount each year for the two succeeding years", so that evidently in the two succeeding years not the ratio but the amount governs. Each lease will contain "approximate conditions fixing the minimum production of phosphates or phosphate rock from the land". Are 'phosphates' and 'phosphate rock' synonymous? The regulations are poorly worded and obscure.

EXPORTATION of gasoline from the port of San Francisco is increasing steadily while the shortage of motor-spirit is causing growing perturbation. During the first four months of 1918 the export of oils, including gasoline, amounted to 65,136,601 gallons valued at \$2,291,294; in the corresponding period of 1919 the total was 43,722,630 gallons valued at \$1,714,766; from

January to April inclusive of this year it was 100,444,971 gallons valued at \$3,929,302. Last year 83% of the oil exported from this port went to Canada; this year, 48.62% had the same destination, and 35.74% went to Chile. In May the export of gasoline reached 4,342,270 gallons, and it was then that the people of California were told that there was a severe shortage, so that they must be content with five gallons at a time. In June the export of gasoline from San Francisco was 4,585,227 gallons, worth \$1,401,731. This does not mean much unless compared with the consumption of gasoline in California, which has averaged 20 million gallons during the first five months of this year. Obviously if 20 to 25% of our output goes abroad, the domestic price is bound to be excessively high.

DIVIDENDS distributed by the gold-mining companies of the Witwatersrand for the first half of the current year aggregate £3,102,975, which compares with £2,576,000 for the first half of 1919 and £3,872,000 for the second half of last year. It must be noted that it is the custom to make a special distribution of profit at the end of the year, so that a comparison between the first half of 1920 and the second half of 1919 would be misleading. As against the corresponding period of 1919, the first half of the current year shows an increase of £526,975 in dividends. This is encouraging, but it is not as much as was to have been expected, having regard to the premium on gold. The amount of gold produced in the respective first half-years has been about the same, while the gross increase of revenue due to the premium has been fully £4,000,000 more during the first six months of 1920 than during the same period of 1919, so that, evidently, nearly seven-eighths of the premium has been wiped out by the increase of expenditure in other directions. Higher wages, the advance in the price of supplies, and banking charges have done their deadly work to a distressing degree, from the shareholder's point of view.

IN a recent dispatch from Philadelphia we read: "Anthracite operators regard \$3.34 per day as a sufficient wage to enable a common laborer in the mines to support himself and family". If by "to support" is meant to purchase food containing the calorific value required to sustain life regardless of quality and variety; and to provide garments capable of preventing death by freezing; and to rent and heat a structure large enough and whole enough to serve as a place to eat and sleep, with no consideration of healthfulness, not to mention comfort or convenience; if these things are what the operators conceive as constituting "support", then \$3.34 per day may be enough. However, had this been their idea, there would have been no point in specifying "for a common laborer" with respect to these essentials to living under the economic conditions of today. A 'common' capitalist would require less than a common laborer because he would need less food; neither he nor his wife do as much work and they could accordingly

get along with a lighter diet. It appears, then, that this \$3.34 is presumed to supply such degree of comfort as, in the eyes of the anthracite producers, a laborer may reasonably expect. They believe, apparently, that it should enable him to purchase the things that make living something more than mere existence; that it should give him such an outlook on life as to make American citizens out of him and his children. We do not believe \$3.34 is nearly enough; nor do we think that the operators who make the statement really believe it is enough. When they make such a statement they invite bitter and justifiable resentment.

THE Joint Conference Committee of the four Founder Societies, which originally constituted Engineering Council, has issued Bulletin No. 1, in which it corrects certain misapprehensions regarding the recently launched Federated American Engineering Societies. The bulletin points out that the administration of the new organization is to be entrusted to American Engineering Council and that the latter is essentially a perpetuation of Engineering Council as it now exists. The suggestion that "no specific business is yet outlined for action by the Council" and that "the Federated Society is so completely nebulous that one cannot commend or condemn it" are refuted in definite terms. The new organization will compete with none of the existing societies nor appropriate any of their functions; it has already come into existence and the unanimous expression of those attending the conference at Washington is sufficient to assure the success of the project. Its purpose is clearly expressed in the constitution: "The object of this organization shall be to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions."

Pike's Peak and Cripple Creek

On July 14 the centenary of the first ascent of Pike's Peak was celebrated at Colorado Springs. The event provokes a retrospect. The soldier explorer, Lieutenant Zebulon M. Pike, who discovered and named the mountain, was not the first to ascend it, that honor being claimed by Dr. Frank James, a member of an expedition under Major Long, who has likewise given his name to one of those hoary sentinels that look down upon the prairie around Denver. Dr. James ascended Pike's Peak on July 14, 1820, starting from Fountain creek, *la fontaine qui bouille*, the spring that bubbles, as it was called by the French trappers long before Manitou Springs came into existence. In honor of the first ascent, Major Long named the mountain James Peak, but as the earlier trappers and plainsmen had called it Pike's Peak as far back as 1810, this name survived, and Dr. James conferred his name upon a peak to the north, not far from that which was named after his chief, overlooking Boulder and Estes Park. Since then a bridle-path, a wagon-road, a railroad, and an automobile road have been built suc-

cessively to the summit for the benefit of the thousands of tourists that go thither every year. A caterpillar tractor reached the summit last year and shortly thereafter an aeroplane sailed over the mountain, so that all the fascination of aloofness and loftiness has been taken from poor old Pike's Peak, but the essential romance remains. In the early years of the last century the snowy crest of this granitic *massif* served as a beacon to the *voyageurs* and explorers who preceded the advance of civilization westward; in 1849 a party of Georgians, led by the Russell brothers, camped on Cherry creek, near the present site of Denver, on their way to Downieville, California. In 1858 some of the members of this party returned to Colorado and uncovered the gold veins of Clear Creek and Gilpin counties. In 1857 a financial panic had broken the moorings of thousands of enterprising spirits and had incited a wave of popular migration westward across the prairies until it broke against the ramparts of the Rocky Mountains. In their progress across the plains the leaders riding in front of the wagon-trains would seek with shaded eye for the first glimpse of the beacon mountain whose white crest on the far horizon gave promise of the land of gold. 'Pike's Peak or Bust', the motto of the adventurers of 1857 and 1858, sounds but mock-heroic in our ears, yet it expresses something of the mingled humor and daring of the men who pierced the unknown wilderness which was then the borderland of the Territory of Kansas. Thus the immigration that marked the birth of Colorado's mining industry was called "the Pike's Peak excitement"; but it expressed a delusion. No noteworthy discoveries of gold were made at that time in the canyons or on the hills surrounding the peak. Important finds of gold and silver ore were made about 70 miles northward, under the protecting shadows of Long and James peaks. Although mines were started in many parts of Colorado during the succeeding twenty years, the silence of the Pike's Peak region remained unbroken. The cattle grazed on the sunny western slopes while towns and railways were being built amid the foothills of the eastern approach, but the prospector found nothing to justify the tradition of gold in the granitic battlements that rose above the line where the pines ceased to climb into the snowfields. Suddenly, in the spring of 1884, rumors came of a great discovery of gold ore on the southern side of Pike's Peak. During the darkness of an April night a horde of prospectors stole swiftly away in obedience to the vague hints that had been scattered among the saloons of Leadville and the neighboring mining camps. Each party aimed to be first on the ground. The dawn of the next day found an excited crowd of four thousand men gathering at the foot of a pine-clad slope. This became known as the Mt. Pisgah fiasco. Among the hills, which like a flock of sheep cluster at the southern base of Pike's Peak, there is a dark cone standing in solitude above its smaller brethren. This is Mt. Pisgah. In 1884 the miners who rushed thither could find no gold save in the prospect-holes made by the first locators. Salting was suspected, the man who had instigated the rush had decamped, an accomplice was caught with a bottle of yellow stuff in his

pocket. It was not whisky, but its quondam antidote, the chloride of gold. Angry feelings found vent in threats of lynching, but in the failure to lay hands on the real perpetrator of the fraud, the affair was turned into a big picnic and a general drunk. A little digging had been done, one or two veins had been uncovered, but the poverty of the ore only added bitterness to the general disappointment. The prospectors disappeared as quickly as they had come. The hillsides resumed the quiet aspect of the cattle range for which they seemed best fitted. Pike's Peak was no mining district; it was left to the cows and the tourists. Nevertheless within ten years Mt. Pisgah overlooked the very streets of the town of Cripple Creek with its 20,000 inhabitants, and on the surrounding ridges the smoking shaft-houses bespoke a long series of rich mines. The lodes of Cripple Creek were discovered in 1891, seven years after the Mt. Pisgah fiasco. During the interval prospectors had wandered over the hills from Colorado Springs and Florissant; indeed, it is said that a shallow shaft, dug by the pioneers even before 1884, was found just above the site of the Victor mine, which was one of the first to rise into importance during the early 'nineties. Some of the cowboys employed by the cattle-men did a little desultory prospecting after the rains, when float is easy to detect. Among these was Robert Womack, who discovered the vein, in Poverty gulch, on which the Gold King mine was based. That was in 1888 or thereabouts; in February 1891 he showed his find to E. M. de la Vergne and F. F. Frisbee, of Colorado Springs, both experienced miners. Then came Stratton's discovery of the Independence on July 4, 1891. That event marked the birth of Cripple Creek, which two years later, in 1893, attracted thousands of miners thrown out of work by the collapse of the silver market. In 1891 Cripple Creek produced \$2060; in 1898, \$13,507,349; in 1900, \$18,147,081. The tradition of Pike's Peak was fulfilled.

Mr. Harding's Acceptance

A man may own a newspaper and yet not know how to write. If Senator Harding's speech of acceptance had been sent by an unknown man to any self-respecting editor, he would have known what to do with it, without hesitation. We know of no better example of an effort to be magniloquent and to fail utterly, of an attempt to use a style wholly unnatural to any sensible man, of a method so affected as to be utterly ludicrous. The gentleman now at the White House must have chortled when he read the effusion of his intended successor. The President wallows in words himself occasionally, but he has enough of literary skill not to permit himself to be bogged in verbiage, as the Senator from Ohio does repeatedly in his recent utterance. The straining at effect is marked not only by repeated use of the abstract instead of the concrete, but also by the introduction of strange words for which even the sanction of the dictionary is lacking. We select one or two of the Senator's purple patches:

"We must stabilize and strive for normalcy, else the inevitable reaction will bring in its train of sufferings, disappointments, and reversals." He means we must strive to restore normal conditions. "When the compact was being written, I do not know whether Europe asked or ambition insistently bestowed." The reference is to the President; he means the ambitious man at Washington. "Ours is an outstanding influential example to the world, whether we cloak it in spoken modesty or magnify it in exaltation." This is worthy of the baboo who announced his mother's death by stating: "The hand that rocked the cradle has kicked the bucket". "Speaking our sympathies, uttering the concurrence of all the people, mindful of our right to dwell amid the good fortunes of rational, conscience-impelled advancement, we hold the majesty of righteous government, with liberty under the law, to be our avoidance of chaos." Presumably the man in the street will think this is high-brow stuff and excuse himself thereby for his inability to understand it; any educated man will recognize it to be piffle, hardly worthy of a high-school sophomore. Apart from the ridiculous phraseology of the speech, we note the most naive evasion of any clear expression of purpose. For example, we are told: "We must not abridge the freedom of speech, the freedom of the press, or the freedom of assembly, because there is no promise in repression", but, "We do hold to the right to crush sedition, to stifle a menacing contempt for law, to stamp out a peril to the safety of the republic, etc." Is it fair to ask how sedition and anarchy are to be checked if freedom to speak, to write, and to assemble are not to be limited by reasonable regulations? Again, as to Mexico, we are told: "It will be simple to have a plain and neighborly understanding; merely an understanding about respecting our borders, about protecting the lives and possessions of American citizens lawfully within the Mexican dominions." Simple, is it? It is the crux of a difficulty that has baffled the best intelligence of two Presidents, Mr. Wilson and Mr. Taft. Simple, indeed? it is the essence of our trouble with Mexico and it is the kernel of our foreign policy. Mr. Harding dismisses the greatest problems with the wave of a rhetorical hand; thus, speaking of economic unrest, he says: "I decline to recognize any conflict of interest among the participants in industry". The interests of the capitalist and the laborer are identical, he proceeds to explain. This is nonsense; can he exorcize the evil spirit or the more substantial facts that menace our industrial progress merely by "declining to recognize" them? Is it only a theory, not a condition, that confronts us? We have criticized frankly, for criticism should be brought to bear upon the utterances of men to whom great power is proposed to be given. It remains to recognize the modesty and sincerity of Mr. Harding's concluding remarks, in which he drops his false diction and talks like an honest man. It is a pity that the spirit of his peroration was not permitted to suffuse his entire speech. We await Governor Cox's speech of acceptance with increasing interest.

DISCUSSION

Recent Metallurgy at Trail, B. C.

The Editor:

Sir—In reply to the letter from P. R. Hines appearing in your issue of July 10, I beg to say that at the time of my visit to Trail it was impressed upon me that both the concentrating plants treating the Sullivan ore, although yielding a satisfactory concentrate, were still in the experimental stage and, for that reason, no exact details of either feed or concentrate could be given; so I contented myself with general principles rather than detailed descriptions of the machinery employed in both plants. In the original draft of my article I went more deeply into details, but when I found I was unable to give the working results, I thought it inconsistent, and so deleted it.

As Mr. Hines states, two poles of a magnet cross the main belt of the Dings magnetic separator and each has a narrow cross-belt, but, as a matter of fact, when I saw the machine in operation the first pole that the pulp crossed was removing practically all the magnetic particles, leaving little or none for the second pole to pick up, and, for that reason, I did not mention the existence of the second pole. The general arrangements of the plant were substantially the same as when Mr. Hines saw it.

The wet magnetic and flotation plants were being run against each other with a view to discovering which is the better process for dressing the Sullivan ore. Recently, I understand, the magnetic plant has been dismantled, so, presumably, the flotation plant has been awarded the palm. This does not mean, of course, that flotation necessarily would be better than magnetic separation for the removal of pyrrhotite from other ores, as without doubt, the wet magnetic machine is capable of extremely good work.

It must be remembered, however, in this connection that the Sullivan ore is an exceedingly complex one, carrying pyrite as well as pyrrhotite, both of which, of course, it is desirable to remove as completely as possible. Added to this, according to the superintendent of the plant, prior to the heat treatment the pyrrhotite is only feebly magnetic. Whether the so-called pyrrhotite is really all pyrrhotite I am inclined to consider doubtful. A careful microscopic analysis of polished surfaces of the ore may reveal other minerals closely associated with the pyrrhotite that at present are not known to exist in the Sullivan ore.

F. H. MASON.

Victoria, B. C., July 16.

Wages, Profits, and Social Ethics

The Editor:

Sir—As stated in an editorial in a recent issue of your paper the present demand of the organized workers on our railways for a minimum annual wage of \$2500 offers not only a serious problem for sociologists but for everyone interested in the continued success of democratic institutions. As late as 1916 the average annual railway wage was under \$700, it is now over \$1400, but as the minimum wage is considerably less than the average in both cases the new demand means at least a doubling of the existing scale and a quadrupling of the rates of 1916. Is there any limit to wage demands or to the possibility of meeting them?

In the simple days of production by hand-labor, which prevailed everywhere till the later 18th century, this question was easy to answer, for it was self-evident that no worker could hope for a greater wage than the value of his own output. If one cobbler could make two pairs of shoes daily while his mate made but one, even an apprentice might calculate that while the first deserved just twice the wages of the other, even the first could not hope for a day's pay larger than the selling price of two pairs of shoes less the cost of the material to make them. But in a modern shoe-factory, organized to realize on the economy of machine-production by a minute division of labor, the problem of apportioning to each worker his rightful share of the total output is far from simple; to solve it requires both a practical knowledge of shoe-making and an intimate acquaintance with political economy and social ethics.

Modern industry is nominally conducted on the competitive system. The price of commodities is fixed by competition between the various producers in the marketplace, the price of labor is set by the competition between several workmen for the same job. Similarly, the interest on capital is fixed by competition between its owners for the notes of an entrepreneur. In the many industries where this basis, of a fair field and no favor for all competitors, actually prevails, the problem of an equitable division of the annual gain between masters and men is greatly simplified. If the owners be allowed the competitive rate of interest on their capital, and the men be granted the competitive rate of wages for each class of work they do, it is clear that any surplus remaining, after making proper allowances for the insurances, depreciation, and amortization of the capital, can easily be divided between masters and men on some mutually satisfactory basis wherever both sides are sufficiently intelligent and

fair-minded. That such is the case has been proved by many profit-sharing experiments in both Europe and America. Two of the most successful recent examples of such practice have recently been described: the first is a large cotton-print factory at Wappinger Falls, N. Y.,¹ the second is the Hydraulic Pressed Steel Co. of Cleveland, Ohio.²

Unfortunately for industrial peace and the attainment of an ideal society, the profits of many enterprises are not limited strictly by free competition, notwithstanding the opinion to the contrary of many superficial economists. Therefore the Cleveland factory's policy of 'telling the truth' and sharing the profits has only a limited range as a social panacea, for it is clear that the mere sharing of unearned profits with the workmen will not right the wrongs of those mulcted by such an enterprise. Moreover, the less the profits are earned by industrial efficiency, the less will the owners have need for the enthusiastic co-operation of their employees, and the less liable will the former be to make the latter the sharers of their financial secrets.

It is the prevalence of this anachronism—vast quantities of unearned profits in a supposedly competitive society—that has made the militant labor-unions useful and even essential for gaining for the workers some share in the new wealth due to improved methods of production. In spite of considerable success in raising the nominal rate of wages for their followers, few labor leaders understand political economy, and they therefore are liable to make impossible demands on employers, or else to gain an increase of wages at the expense of an increase of commodity prices, and thus perhaps injure the workers more in their consuming capacity than they benefit them as wage-earners. For scrutinizing the possibility of raising wages by union effort, all industries must be divided into six classes: I, universally competitive; II, nationally competitive; III, locally competitive; IV, legally monopolistic with competitive prices; V, legally monopolistic with monopolistic prices; and, VI, artificially monopolistic.

Class I. Universal competition may be illustrated by cotton-cloth manufacture, in any free-trade country like England, where a world-wide competition keeps the difference between the cost and the selling price of the product so small that the employer has little or no surplus, above the necessary cost for his capital and supervision, for the increase of wages. If he raises the selling price for his cloth, he will lose his customers. Unions therefore must increase the daily output of their members if they wish higher wages in this class of industry. As in such an endeavor the financial interests of the employer coincide with those of the men and the community, we have here no natural obstacle to impede either the introduction of industrial democracy or the opening of the books to the general public.

Class II. National competition may be illustrated by

woolen-cloth manufacture in any country protecting it from foreign competition by an import duty, like the United States. In this class the possible surplus for raising wages would be the difference between the existing cost of production, and the foreign price plus transportation and import duty; because a combine of all the employers could advance the selling price of their cloth to this latter sum without danger of losing their home market. As soon as our woolen-mills have sufficient capacity to supply the domestic demand, their selling price will be set by competition among themselves and tend to fall below the price of imported cloth. While this status of free competition prevails, our protected manufacturers will have just as much to gain from industrial democracy and no more to fear from their balance-sheets becoming public property than have their counterparts in free-trade England. It is only when they abandon competition and combine, so as to fix their price with reference to the protective tariff-wall that they can acquire an unearned profit, and must needs become autocratic and mysterious, in order to defend themselves from prying labor-leaders on the one hand and from tariff-revising statesmen on the other.

Class III. Local competition is illustrated by the building-trades of a city, where the only limit to an advance in the prices for construction is the danger that contractors and workmen will be brought in from a nearby city to do the work. There is therefore a strong temptation for local contractors to form a combine, so as to advance their prices to this natural limit and thus gain an unearned or monopoly profit. Such a combine, in order better to defend itself from underbidding by 'scab' contractors and hold-up strikes by labor leaders, has found it usually advantageous to establish the closed shop and divide its loot with its union workmen. In some cases, especially in plumbing, the supply-houses are also in the combine and will sell their goods only to its members. Among our big cities, Chicago and San Francisco have been notorious for such building-rings, which have stopped at no means, fair or foul, to maintain their monopoly. As such a ring greatly increases the cost of houses, it means higher rents for everyone, including the workmen, of whom only a small fraction belong to the building-unions and get a compensatory wage. As a contractors' combine shares both its profits and its secrets with its workmen, it may be considered as the application of industrial democracy to predacity, the public being the prey.

Class IV. Legal monopoly with competitive prices is based on the ownership of all classes of land except that of public utilities.³ In the popular concept, nothing is a monopoly that cannot set the price of its product; but, technically, the exclusive possession of national resources, conferred by a land-title, represent a monopoly irrespective of the land's relation to commodity markets. Economic rent, or the income arising from the land itself apart from its improvements, is unearned by the indi-

¹'Industrial Democracy at Wappinger Falls', 'Literary Digest', March 6, 1920, p. 115.

²'Tell the Truth', 'The Outlook', Jan. 28, 1920, p. 148.

³'Mr. Ingalls and Walkerian Economics', by the writer, 'M. & S. P.', Vol. 119, p. 627.

vidual land-owner, for it arises solely from some quality inherent in the valuable land that enables it to yield a residuum after all the necessary costs for the use of labor and capital to render it productive have been paid. While large areas of privately-owned land are so lean as to be rentless, the superior lands yield an income of economic rent, which comprises the bulk of the wealth engendered by a community working as a social unit. Any enterprise of this class, therefore, which owns superior land and employs many workmen—such as numerous mining and lumber companies—is sure to yield a monopoly profit (rent) which will arouse the cupidity of labor leaders if they discover its existence. Any share of this profit that a labor leader can secure for his followers will mean a net increase in wages, since here the profit (rent) is not due to a monopoly price but to the superiority of the productive factor (land) and therefore the cost of commodities is unaffected, be its recipient land-owner or laborer. It is thus to the interest of this class of enterprises, as land-owners, to conceal carefully all details of their capitalization and income from their employees; while as producers their interest may lie in the opposite direction so as to improve their labor efficiency by profit-sharing. The greater the rent in proportion to the total profit, the more will the former policy outweigh the latter in the practice of an enterprise. As rent is an unearned profit authorized by law, the great land-owners are much less vulnerable to militant unionism than are the illegal monopolists of Class VI. In the United States before the Great War, it was only where the rich landed enterprises employed a large proportion of the voting population and this was well organized—as in the Rocky Mountain mining districts—that they were obliged to pay out any considerable share of their rental profit in the form of higher wages.

Class V. Legal monopoly with monopolistic prices includes three sub-classes of property: (a) Special lands of limited areas so that the world's price for their product can be fixed by any owner who may have acquired control of the bulk of them, for example, the Diamond Trust of South Africa, the Borax Trust of England, and the Henequen Trust of Yucatan. In countries with a protective tariff it suffices for one owner to acquire control of the domestic lands in order to fix prices independent of national competition, for example, the Aluminum Company of America with its ownership of bauxite deposits. (b) Public utilities such as railways, telegraphs, telephones, oil, gas, and electric trunk-lines. Here, owing to the franchises required and the cost of duplication, an enterprise can largely fix its own prices for service at whatever 'the traffic will bear'. This condition prevails except at 'competitive points', where two or more enterprises may offer the public the same service, and in countries where the rates charged by public utilities are strictly controlled by charter or by a government commission. (c) Patents for invention, as granted by the United States, confer a monopoly for the manufacture and sale of the article upon the grantee, and consequently free the latter from competition in fixing his selling price.

From the above, it is evident that the unearned profits of sub-classes (a) and (b) proceed partly from the legal advantage conferred by the ownership of superior land (mines or rights of way) and partly from the power of charging prices for the output independent of the natural regulator called competition. In sub-class (c) the unearned profit proceeds solely from this latter power, for any reasonable royalty paid to the inventor should be regarded as merely a fitting reward for his services to society. The relation of labor to the enterprises of sub-class (a) duplicates its relation to those of Class IV in so far as the unearned profit proceeds from superior land; where such profit proceeds from the enterprise's power to fix prices, any share of this obtained by labor will result in a higher price for the output to the consumer whenever the increase will mean more of an annual income for the owner. The last statement likewise holds true in the case of enterprises of sub-class (c) owning patent rights; so, in both cases, the gain of the monopolist's workmen may mean a loss for the consumers. The public utilities of sub-class (b) resemble sub-class (a) in their relation to labor, and have a relation to the public similar in kind but widely different in degree. On American railways a general increase of wages during the Great War has meant the ruin of thousands of investors in their securities, while should the investors be compensated by a corresponding increase of rates for service, the public must meet the expense in the form of dearer commodities.

Class VI. While artificial monopolies for the purpose of suppressing competition may be formed among enterprises of Class II or III, as already described; the largest and most profitable ones, like the Standard Oil, the Beef Trust, and the United Shoe Machinery Co., have owed their power chiefly to the ownership or control of monopolies of Class V, by which they gain advantages not enjoyed by their rivals. A recent demonstration of this fact is afforded by the surprising number of independent oil-refineries that have sprung up in the United States since the pipe-lines of the Standard Oil group were declared to be common carriers a few years ago.

In normal times, artificial monopolies of a temporary nature have been features of the commodity exchanges. These 'corners' of the market have also depended for success upon secret alliances with the legal monopolies of Class V, through which they enjoy special favors, usually in transportation. In wheat, the *coups* are commonly made by speculators controlling a string of elevators closely identified with some railway system.

Since 1914 the dislocation of production, caused by the Great War, has rendered it easy to corner many commodities that formerly were too plentiful to permit of such an operation. This game has become so simple and profitable that few merchants can resist the temptation to take a hand, so we have coined a new word, 'profiteering', to describe it. The hue and cry due to this merciless muleting of the consumers has driven the politicians nearly frantic, and the profiteers are being combated by remedies as wide apart as jail sentences and overall clubs.

In so far as the unearned profits of the enterprises of Class VI are concerned, they accrue regardless of efficiency in labor and there is therefore nothing to be gained directly by the introduction of profit-sharing to balance its cost to the owners, but operating as the latter do in defiance of both the Common Law against combinations and the Federal statute against restraint of trade—Sherman Anti-Trust law—many of them realize their political weakness and have been wise enough to pay their workmen the best of going wages, so as to avoid strikes and their frequent accompaniment of dangerous investigations of business secrets by meddling politicians.

The above remarks have proved, I hope, that labor-unions may often increase their members' wages without augmenting either their production or the cost of living. A successful attack on unearned profits by militant unionism will never increase living costs where the profiteers belong to Class IV and seldom do so when they belong to Classes V or VI. Nevertheless, these battles between masters and men cause vast inconvenience to the public and much needless suffering to innocent bystanders, however closely they may observe the laws against physical violence. Whichever side succeeds in gobbling the lion's share of the unearned profits, which form the bone of contention, the practical question is: Has the struggle been unavoidable and the ensuing result ethical? It is just here that we have a use for social ethics brought up to date—for in this subject there are few teachers whose knowledge of industrial relations is of a later period than the early 18th century or who possess a sufficient mastery of political economy to analyze correctly such relations as they may now encounter.

The Industrial Court recently established by the State of Kansas proposes to protect the public from further labor wars by taking over for State operation any essential industry whose owners or employees refuse to obey the Court's rulings and suspend work. The Court has power to alter any labor contract. Picketing and black-listing are equally outlawed, while striking or calling a strike are made punishable by heavy fines and imprisonment. A student of history can feel no great certainty for the success of this Court. Lacking any intelligent code of social ethics on which to base its decisions, its chief effect will be a partial transfer of the labor war from the industrial to the political field. Each contestant will strive to name its own partisans as judges, so that labor will be oppressed or capital mulcted according to whether capital or labor chooses the State's governor who makes the appointments.

While private monopoly has been execrated by American politicians for half a century and multitudinous laws have been framed to suppress it, little has been accomplished even to restrain its operations except in the case of certain price-fixing monopolies—the public utilities—of Class VI. But as the land-value or monopoly element of all public utilities comprises scarcely 25% of the total land-values of the country, the campaign against monopoly can scarcely be considered a brilliant success, even without considering the many artificial monopolies of

Class VI that still continue to flourish. Indeed, no marked change can be expected until the public ceases to regard money as the badge of distinction and becomes familiar with the simple economic laws that govern the distribution of wealth.

If a monopolist does not earn his profits in the fair field of a competitive market, it is clear that his profits proceed from the earnings of somebody else and are therefore stealings, however much the fact may be camouflaged by property laws inherited from the conditions of a bygone age. Similarly, a militant unionist is a thief when he forces his employer to pay him as wages several times the value of his contribution in labor to wealth production; for such an excess wage must mean either the mulcting of the consumer, by high prices, or the private absorption of economic rent—the rightful heritage of the nation under our existing political system, if justice were done.⁴ So it is hardly consistent for the bourgeois to applaud an investor for drawing out \$1000 from a \$10 investment, and condemn a proletarian who demands \$10 for \$2 worth of labor.

Anyone who has resided in a medieval country like Mexico must realize how far modern America has advanced beyond the ethical code of the 16th century. Nevertheless, our code is still notably archaic in its lack of provision for an equitable distribution of wealth in a political democracy working under the factory system. This defect—hitherto marked by fortuitous conditions⁵—is becoming glaringly evident as an aftermath of the social dislocation resulting from the Great War and must be remedied if American ideals of freedom of opportunity are to be preserved. The remedy can be readily prescribed from the proved principles of political economy, but at present our practical politicians have no knowledge of, nor use for, this science and its adepts.

ROBERT B. BRINSMADE.

Ixmiquilpan, Mexico, July 11.

ONLY a large deposit of mica, favorably situated with regard to transportation and a grinding-mill, can be worked solely as a source of scrap-mica for grinding. Most mica mines must also yield good sheet-mica to make the mining profitable. Mica to be of value as sheet must yield rectangles at least $1\frac{1}{2}$ by 2 in. that must split easily and evenly, be free from cracks, markings, and fracture lines, and be reasonably free from specks or foreign mineral matter. The size stated is the smallest rectangular size which is salable as uncut sheet, and the rough-trimmed mica sheet must be nearly twice as large to yield the rectangle stated. In order to be profitable most deposits must also contain some mica larger than $1\frac{1}{2}$ by 2 in., according to the U. S. Geological Survey. Good sheet-mica should be so flexible that a sheet one-thousandth of an inch thick can readily be bent into a cylinder one-quarter of an inch in diameter without showing any crack.

A History of Mine-Fires in the South-West—Part I

By CHARLES A. MITKE

INTRODUCTION. The problems that primarily confront the manager of a mine are those of ore-reserves, methods of stoping, transportation, equipment, supplies of labor and materials. While these absorb practically the entire attention of the staff, they fail to include the possibility of a fire underground, which may destroy valuable property in a short time and result in a complete shut-down of the mine for an indefinite period. Drifts and stopes may be caved in a few hours by the burning of timbers, shafts may be destroyed and manways ruined, to say nothing of the loss of lives or the number of men invalidated by breathing poisonous gases in the process of fighting fire.

The erection of a large building is never undertaken without preparing careful plans for protection against fire and providing a full equipment of fire-fighting apparatus. In addition to this, the owner carries heavy insurance to reimburse him in the event that all his prearranged plans for preventing or fighting the fire fail at the critical moment. In the mining industry, however, there are mines of an estimated value of from \$100,000 to \$50,000,000 that lack an adequate system of fire-protection, that have little or no equipment available in case a fire breaks out, and, of course, no fire insurance underground, for as yet no insurance company has entered this field. Should an outbreak occur, there is not only the danger of destroying timber, which often results in extensive caving, but frequently stopes must be sealed, thus preventing the mining of large bodies of ore for years. It is a well known fact that some of the big copper mines of this country contain large bodies of pay-ore which have been sealed for many years, and there are a few instances where even high-grade ore has been locked up and lost temporarily on account of dormant fires.

The principal reason for sealing mine-fires is to localize them and so permit the rest of the mine to be operated in safety. This practice was followed wherever possible in the past, and has proved especially successful in orebodies stoped by the square-set method. Under such conditions, the filling of stopes with waste at intervals, as the ore is removed, usually prevents the ground from caving to surface. In the top-slice system, however, the conditions are entirely different. With few exceptions, it is impossible to seal hermetically a stope that has been worked by top-slicing, as, this being a caving method, the overburden generally breaks to surface and allows the air to find its way down to the fire, while the heated gases work their way upward through the mat of timber. In a few exceptional cases, where the overburden of the top-slice has not broken to surface, a seal may be effective. This, however, presents a dangerous condition, as large blocks of ground from the arched overburden may drop at any

time and crush the top-slice, closing all drifts and manways.

It is the general impression that a fire cannot occur in a stope operated by the shrinkage system, as this method of mining requires very little timber. There are cases on record, however, where the cribbings in shrinkage stopes have taken fire, the flames following the timbered raises to the haulage-levels and ultimately causing the caving of both the stope and the haulage-level.

While it may be possible to abandon and seal that part of the orebody that is on fire in mines containing large bodies of low-grade ore, the management of high-grade properties cannot afford to follow this method of procedure, as the ore usually occurs in a very limited quantity, and it is absolutely necessary to work out some means of handling the fire in order to continue operations without curtailing production.

The following is a brief account of some of the fires that have occurred during recent years:

BISBEE-WARREN DISTRICT

One of the most serious fires in this district was that in the Lowell mine of the Copper Queen branch of the Phelps Dodge Corporation, which started in January 1911, and is sealed up at the present time. The place where the fire originated is between the 1000-ft. and 1200-ft. levels, and was mined by the square-set system. The orebody contained a high percentage of sulphur and undoubtedly some pyrite had been lost in the waste. While it has been the general practice in the South-West for a number of years never to put any pyrite in the filling of stopes, nevertheless, with the most careful mining, there are times in handling fine material when it is impracticable to prevent a few tons of pyrite from escaping into the waste. Even with excellent supervision, a careless miner may allow this small amount to run into the fill unnoticed. This small amount of pyrite, coming in contact with timbers, under pressure, is sufficient to produce the heat required to start a fire.

At the Lowell, the progress of stoping naturally caused considerable friction between the blocks of sulphides, which created a great deal of heat. Oxidation of pyrite and timber was also an important factor. The temperature increased until the timbers took fire, and they in turn started a fire in the sulphide ore. The resulting gases, such as SO_2 and the distillation products of wood, came to the upcast shaft and caused considerable damage by corroding the heads of lag-screws in the guides, with the consequence that some of the guides fell out and jammed one of the cages near the 600-ft. level, which put it out of commission, while the other cage was in danger of meeting the same fate at almost any time.

In 1911, at the time this fire started, the Lowell mine had only one shaft, which, as stated above, was an up-cast, the intake air coming from an adjoining division (the Sacramento), and as the fire could not be reached conveniently from below, it was absolutely necessary to make an attack from above. This implied the use of the shaft, and made repair-work essential before fire-fighting could be organized. It was therefore decided to start with the free cage and commence repairing the shaft from surface to the 800-ft. level, the place where the gases first entered the shaft.

On account of the large amount of carbon di-oxide and sulphur di-oxide, the men were compelled to use oxygen helmets while carrying on the repair-work, which consisted of putting in 500 lag-screws; taking out an old electric cable, which had worked its way across the shaft and was beneath the free cage; chopping out the cage, which, owing to the falling out of the guides, had jammed hard against the timbers; and putting in 150 ft. of new guides—quite a dangerous and extensive piece of work to be accomplished by men wearing oxygen helmets.

Owing to the unusual circumstances, the men, while on duty eight hours, were only asked to perform actual service for two hours of the day. On account of the heat and gas, the time of the helmet-crew was originally divided as follows: 20 minutes of actual work in the shaft, and from 40 to 50 minutes resting and overhauling the apparatus. Great difficulty was faced by the men using the breathing-apparatus in the hot and gaseous atmosphere, as the sulphur di-oxide, in combination with excessive natural perspiration, formed sulphurous acid, and in a comparatively short time the men had large burns all over their bodies. Finally, the total working-time of two hours per day in actual work had to be cut down to an hour and a half, and some of the men had to remain idle in order to recover from their burns.

On a few occasions, while two men were on the cage between the 400-ft. and 600-ft. levels, the breathing-apparatus of one of them gave out, making it immediately necessary for the other to pull the signals and bring his companion to surface. In several cases, the men brought to surface in this condition were partly unconscious when the apparatus was removed, so that artificial respiration had to be performed.

After the shaft was repaired and the cages again in operation, so that supplies could be taken to the different levels, it was not long before the fire was successfully sealed. As this ore is not needed for present production and its recovery would involve a large expenditure, the fire-area will not be re-opened for some time to come.

On December 2, 1915, fire again broke out in a stope adjacent to the one described above. As the men had just gone on shift, the bosses were instructed to bring the entire force back to the different shaft-stations immediately. The fire spread rapidly and the smoke and gas penetrated nearly all the workings between the 900-ft. and 1300-ft. levels during the first day. Part of the gas escaped through the Oliver and Cole mines of the Calumet & Arizona Mining Co., where six men were overcome.

At the time of the first fire in this mine (Lowell) there was but one outlet to surface, namely, the shaft that had to be repaired (the intake being from an adjoining mine, the Sacramento). It was impracticable therefore to use mechanical ventilation, and all repairs and fire-fighting had necessarily to be done by helmet-men. After this first fire was sealed, and prior to the new outbreak, a raise had been put to surface for the purpose of having a permanent outlet for smoke and gas, and a system of mechanical ventilation had also been established. When, therefore, the fire broke out a second time, the general mechanical ventilating system was kept in continuous operation, and an auxiliary system quickly was introduced to take care of the fire-stope. Aside from 10-in. blowers and ventilating-pipe, a 3-ft. disc-fan was used, which furnished a large volume of air at a low pressure. This created a better atmosphere and permitted the larger part of the work of fire-fighting to be done without the use of oxygen apparatus.

Within two and a half days, the fire was sealed, and no further outbreaks have occurred.

In each case, after the fires were sealed, water was turned in through the bulkheads; this finally collected in a drift on the 1300-ft. level, known as 'Copper River'. A small precipitating-plant on this level has yielded handsome returns.

Other important outbreaks, as regards size and danger to life and property, were the several fires in the Holbrook mine, of the same company.

In the early part of 1912, a district in this mine, between the 200-ft. and 400-ft. levels, known as the 'Neptune', became exceedingly hot, but the volume of smoke and gas was small. Toward the end of the year, however, an outbreak occurred and the fire-area was sealed without delay.

On July 13, 1913, another fire broke out in the Holbrook. This was located in a square-set stope between the 500-ft. and 600-ft. levels. At that time the mine was ventilated by natural means. The smoke and gas proceeded along the 600-ft. level to the Spray, Lowell, and Sacramento, and caused an immediate shut-down of these three mines. During the first hour, while in search of the origin of the fire, the assistant-superintendent and one of the shift-bosses were overcome with gas, while the mine-superintendent became delirious. These men were rescued with great difficulty. Owing to the foreman's presence of mind, the pulmotor and oxygen apparatus had been sent previously to the mine, and as the men were brought out through the raise from the 500-ft. level, the pulmotor was immediately applied until they recovered sufficiently to be sent to the hospital. Exploratory work was continued until the fire was reached. A plan was then formulated to seal all the drifts and raises leading from the fire-stope. Temporary brattices served to check the gas, so the men could work without using the oxygen apparatus. Finally, cement bulkheads were built. Two churn-drill holes were put down from the surface, immediately over the fire-stope, and water turned into them. After several months, the fire-area was opened

and it was found possible to extinguish the smoldering remnant from the 500-ft. level.

On October 29, 1915, the third Holbrook fire occurred. Smoke was detected coming out of an old stack near the site of the former change-room. This stack had been erected some years before to ventilate an earlier fire-area. The cause of the new fire was the heat generated by the

three men were overcome while attempting to put up brattices, in order to turn the gas to other outlets, but they recovered when taken into fresh air. Most of the ore had been stoped from this area by the square-set method about ten years before, and at that time some pyrite and old timber had probably found its way into the fill. In the course of time the whole area became hot

and the temperature increased until timber-gases were given off. This part of the mine was quickly sealed and some water admitted from above, which apparently had the effect of cooling the ground, for the gas decreased. However, on April 29, 1915 (just a year later), the gas began coming out on the 800-ft. level, immediately over the old fire-area, and it was then found necessary to outline a campaign for lowering the temperature of the entire block of ground, in order to eliminate the dangers arising from continual outbreaks of gas.

A main drift was driven over the heated zone on the 800-ft. level and cross-cuts branching from it at right angles every 25 ft. The faces were so hot that they had to be sprayed thoroughly before the men could commence work. Auxiliary systems of ventilation also had to be used. The work was continued over a period of a year and a half, during which

sealed fire-area; this had penetrated through waste until it reached a raise between the 200-ft. and 300-ft. levels, where smoke and gas burst out, filling the raise and finding their way to surface through the stack. Prior to this outbreak, a mechanical system had been installed to ventilate the lower levels, the natural air currents being depended upon to ventilate the upper workings. After arranging the ventilation so that no smoke or gas would be forced down to the lower levels, water was turned into the raise to put out the fire, then pipes were driven from the raise into the surrounding waste, and connected to water-lines in order to cool all the ground in the immediate vicinity. Midway between the 200-ft. and 300-ft. levels intermediate drifts were started from this raise into the hottest part of the old fills. These were flooded from time to time until the entire area finally was leached. The copper water from this fire-area, as well as that from other areas in the Uncle Sam and Czar divisions, is pumped to surface, and flumed to the leaching-plant, where the copper is recovered.

On April 29, 1914, gas was noticed on the 1000-ft. level of the Gardner division of the Copper Queen mine, at 150 ft. from the Gardner shaft. The following day

FIG. 1. THE LOWELL SHAFT OF THE COPPER QUEEN MINE

FIG. 2. TWO MEMBERS OF THE HELMET-CREW ABOUT TO ENTER THE CAGE AT THE LOWELL MINE

time there was a great reduction in the temperature, and the fire-area has now cooled to such a degree that no gas is given off and there is no immediate danger of further outbreak.

In February 1919 a complete shut-down was caused at the Shattuck-Arizona mine by an underground fire

between the 700-ft. and 800-ft. levels in the mine, in the abandoned and filled portion of the low-grade sulphide orebody. Gas and dense sulphur smoke penetrated the workings above the 800-ft. level, making operations unsafe. A force of 50 men was trained in the use of oxygen-helmets. Bulkheads were built to confine the burning area, and preparations were made to flood the workings below the 700-ft. level. To accomplish this, it was necessary to pump into the mine more than 25 million gallons of water. Wood and sulphur gases ceased to escape when the water-level reached a point eight feet below the 700-ft. level. Unwatering of the flooded part of the mine began in September 1919, and mining of copper ore was resumed on a small scale in that month. The workings are now free of water and a force of men is engaged in re-timbering the caved portions of the 800 and 900-ft. levels.*

On the night of March 27, 1920, a fire started on the 1300-ft. level of the Briggs mine of the Calumet & Arizona Mining Co. A large body of pyrite containing masses of copper-sulphide ore had been stoped by the square-set method for a number of years. Owing to the large amount of sulphur in the ore, it was recognized that this was a dangerous area, which sooner or later might take fire. In order to prevent this, a system of ventilation was devised to force large volumes of cool air through the prospective fire-area. This system was established four years ago, and had the effect of cooling the area considerably. Arrangements were made also for the coursing of smoke and gas from a possible fire through an old abandoned raise and level, and thence to surface. At that time it was obvious that as additional timber was taken down the mine each year, and the stoping operations enlarged, the frictional area between the stoped parts and the pyrite would also increase, as well as the amount of heat generated.

Prior to March 27 the area was fairly cool and no fire was looked for at that time, as the men had been working near the point where the outbreak occurred, and one of the bosses had gone through only an hour before. However, the gases that are the result of distillation products from timber were noticed. Simultaneously with the characteristic odor, there was a general movement of ground over old filled stopes, which caused a great deal of friction between the old waste and the edges of the pyritic ore adjacent to the old fills. This, in turn, caused much heat so that the timbers of the drifts on the 1300-ft. level ignited simultaneously and soon developed into a terrific fire. Thanks to the co-operative effort of the mine organization, excellent work was performed in extinguishing the fire in less than 24 hours. After the fire had been extinguished, a small amount of sulphide ore, under a mass of caved material, was still burning. Within a few days this was also extinguished by the application of air and water. The mine was idle only two days, and the operating department deserves a great deal of credit, as conditions were such that this might easily have developed into one of the largest fires

that have yet occurred in the South-West and might have caused enormous loss to the company. However, through the foresight of the management in establishing a complete ventilating system to meet just such an emergency, a catastrophe was averted.

A second outbreak occurred on May 2, 1920, but this was not nearly as serious as the former fire and was soon under control. In order to cope with the danger, further precautionary measures are being taken by sinking a new shaft from surface to the 770-ft. level, so as to have a direct outlet to surface from the sulphide orebody. Additional fans will also be installed so that higher air-pressures can be built up to force still larger volumes of air through the hot area.

During the last five years there were two shaft-fires in the Bisbee-Warren district, a small one at the Briggs mine of the Calumet & Arizona Mining Co., which was extinguished in a few minutes, and the other in the White Tail Deer shaft of the Copper Queen. The latter shaft was entirely destroyed to the 150-ft. level, as well as the head-frame and surface buildings, the flames rising as high as 50 ft. above the collar of the shaft. Although this shaft was down to the 300-ft. level, there were no workings below the 150-ft. station, and even though the fire had a good start, nevertheless, on account of lack of air, it extinguished itself at the first level.

Prior to 1911, a large fire broke out near the side-lines of the Irish Mag mine of the Calumet & Arizona and the Spray mine of the Copper Queen, by which more than 30 men were overcome with gas. Fortunately, there were no fatalities in getting the fire under control. A dormant fire exists in the Irish Mag mine, adjoining the side-lines of the Gardner mine of the Copper Queen, near the fire just mentioned. Fire-areas also exist in other parts of the Bisbee-Warren district, but these are well under control and are unlikely to give any immediate trouble.

CANANEA, MEXICO

During July 1914, owing to political and labor troubles, the mines at Cananea were closed down. On the 23rd of that month, fire broke out in at least nine different places in two of the large mines, the Veta Grande and Oversight. Four of these fires were put out immediately by the foreman and shift-bosses, but the remaining five—two in the Oversight and three in the Veta Grande—were soon beyond control. Several helmet teams from the Copper Queen at Bisbee were sent to Cananea; when the men arrived, the Oversight shaft was afire, and smoke and gas were coming out of the main tunnel to surface, indicating that the fire in the shaft had also set fire to the tunnel. The powder magazine was situated at a point half-way between the entrance to the tunnel and the shaft.

Extinguishment of the fire at first appeared impossible, so the removal of the powder was attempted. As no fans were available, the helmet team blasted the compressed-air line about fifty feet from the tunnel entrance, which resulted in reversing the air currents. Within a few minutes the men were able to work without helmets

*Annual report, Shattuck-Arizona Mining Co.

FIG. 3. PILARES SHAFT OF THE MOCTEZUMA COPPER CO., IN SONORA

in removing the powder from the magazine, and, later, were successful in extinguishing the fire.

All efforts to save the Oversight shaft, however, were unsuccessful, as the fire had gained too great a start before the men arrived on the ground. In a few places the fire spread from the shaft until it entered the timbered mat over some of the top-splice stopes. These had to be bulkheaded and the seal made as effective as possible.

In the Veta Grande, the fire entered square-set workings adjoining the large shrinkage-stopos on the 200-ft. level. This was extremely dangerous, because caving resulted from the shrinkage-stopos as the square-set workings burned out. Practically all the fire-fighting had to be done by men using oxygen hel-

metts. The fact that mechanical ventilation was not in use in these mines added to the peril because the gases were liable to go in any direction.

Eventually the fire in the Veta Grande extended to the 300-ft. level and all the haulage-drifts beneath the fire-stopos had to be bulkheaded. Water was admitted from above, wherever possible, until the fire-area had been reduced to a few small stopos. As conditions in Mexico at that time were such that the mines could not be operated, the remaining fire-areas were sealed.

In view of the large num-

FIG. 5. CAVED GROUND (AT BACK OF THESE HOUSES) OVER TOP-SPLICE STOPE OF THE COPPER MOUNTAIN MINE

ber of fires, and also the fact that so many men were employed, who were gaining their first experience in fighting mine-fires, it was extremely fortunate that no lives were lost and no one seriously injured.

NACOAARI, MEXICO

At the Pilares mine of the Moctezuma Copper Co., near Nacoari, two small shaft-fires occurred during the early part of 1918, one on the 800-ft. level of the Gaudelupe shaft and the other on the 500-ft. station of the Pilares shaft. Both these were discovered immediately and ex-

tinguished promptly. They were caused probably by defective insulation of electric wiring.

CLIFTON-MORENCI-METCALF DISTRICT

On September 25, 1916, fire was discovered in the Clay mine of the Arizona Copper Co. at Morenci. This mine was ventilated solely by natural means. Helmet-crews went into the mine as far as the large top-slice stope, known as the Harrison, and found a fire immediately beneath this stope on the adit-level. Preparations were then made to put water on the fire, but the ground surrounding it began to cave, extinguishing the fire in the adit, but not that portion of it which had already passed through the stope and entered the timbered mat above the top slice. It was impossible to reach this, so that the entire mine filled with gas, making bulkheading extremely difficult under conditions of natural ventilation.

A temporary system of mechanical ventilation was then devised, using compressed air, a number of small blowers, a 3-ft. disc-fan, and one larger fan that was hastily built in the company's shops. These fans and compressed-air jets were utilized to clear the workings of smoke and gas, so as to make it possible to reach the Harrison stope, where hose-connections were made in order to force water into the timbered mat. This was a difficult as well as a dangerous operation; on account of the caves that were continually taking place as the bottom of the mat burned out. As the work progressed, it became evident that the visible fire was only the lower extension of a larger one higher in the mat.

By this time another fire had been discovered on the first level of the Clay shaft, adjoining the Harrison stope, which made it necessary to seal the entire fire-area. This required the construction of a number of cement bulkheads on the first, second, and third adit-levels, after which the fire-area remained sealed for some time.

About six months later, some exploratory work was done over the timbered mat above the fire-area, for the purpose of learning whether any of the peaks of flame that had penetrated the mat were still burning, because, in this event, their presence would be indicated by great heat on this upper level. However, through labor difficulties, this work had to be abandoned temporarily.

In November 1917, the above-mentioned level and the entire fire-area were again re-opened under pressure and thoroughly examined. Gas analyses of the atmosphere within the bulkheads showed the presence of a large amount of carbon di-oxide. The fact that mining had only recently been commenced in the top slice and the ground had not yet broken to surface had made it possible to seal the stope. The result was a depletion of the oxygen in the air with a corresponding increase in the amount of carbon di-oxide, which had the effect of extinguishing the fire.

The Harrison stope was then rehabilitated, and later work has shown that there is a complete absence of existing fire, latent heat, or resulting gas.

On October 16, 1916, a fire was detected in a top-slice stope in the Copper Mountain mine of the Morenci

branch of the Phelps Dodge Corporation. A large amount of smoke and gas poured from this stope through the Copper Mountain adit. That same evening, and for some time thereafter, a great deal of gas was noticed in the town of Morenci, in the vicinity of the post-office, and some of the residents near the mouth of the Copper Mountain adit had to abandon their homes temporarily. After investigation, it was found that the fire was in the timbered mat, immediately over the stope in question. When efforts failed to extinguish it from below, this plan was abandoned, and bulkheads were built in raises on the 300-ft. level, and water turned in from above, so as to flood the ground and raise the water-level as much as possible. While this was being done, an effort was also made to extinguish the fire from above by driving drifts and cross-cuts over the fire-area. The rock was hard, so that winzes could be sunk from the different cross-cuts and water turned into them at once. As all work in the drifts, cross-cuts, and winzes was carried on in hot ground, blowers had to be used to force large volumes of cool air into the headings. The principal difficulty in fighting this fire was that the ground above was caved to surface, thus allowing some circulation of air. While the active fire was extinguished within a short time, it was several years before the heated ground showed the effects of the application of air and water.

(To be continued)

THERE is considerable popular misapprehension regarding the occurrence of petroleum. It is sometimes said that oil occurs below the surface of the ground in some regions just as water does in others. This would mean that a well in an oil region is as likely to strike petroleum as a well in a water-bearing region is likely to strike water—that the oil is distributed in an almost continuous sheet beneath extensive parts of the country. This is not true. Another statement frequently heard is that the oil forms an underground 'stream', and that a lucky location for a well must lie over that 'stream'. Expensive and fruitless drilling has repeatedly shown that such 'streams' of oil do not exist. A belief that is strongly held in some parts of the country is that oil pools are connected—that some channel connects the pools in an oil region. This belief is absolutely disproved by the ranks of barren wells that encircle practically every producing oil pool in the world. Another wrong idea is that petroleum occurs in underground ponds or lakes. In fact prospectuses of some oil companies refer to "lakes and rivers of oil", giving the idea of great caverns filled with oil. Not a single such cavern has been found in any oil-fields in the United States. Oil is really contained in the tiny openings between grains of sand, in the pores and crevices of a crystalline limestone, or, as in the largest wells, in the comparatively small openings of a porous rock. The depth at which oil may be found is apparently limited only by the depth to which men can sink a hole. In some fields productive oil-wells are only 100 ft. deep. In others most of the wells are 2000 ft. deep, and many are more than 4000 feet.

Science and Industry

By A. W. ALLEN

Science is knowledge—complete knowledge, knowledge without boundaries, knowledge that brooks no restrictions. It can be made the beacon-light of industry, but not the servant of commercialism. It can be made to point the way to greater and still greater material achievement; but those who would gamble with science as they would with stocks or shares on the Exchange or on the Curb are liable to find an instance where the law of averages does not apply. Luck in a game of chance is just luck. Luck in science—there is no such thing; for with a real search for enlightenment the result is never too great to be unexpected nor too insignificant to be valueless.

No scientist worthy of the name fails to 'make a job' of an investigation—he covers the ground thoroughly. Much of his work appears to the uninitiated to be of no tangible value. Much appears to the superficial observer to lead nowhere. But the scientist knows differently, for he and he alone can gauge the worth of gossamer threads of fact and theory—threads of inspiration that may be woven into chains of evidence leading to great discoveries.

It is the failure to look beneath the surface—the eternal measurement of data and results in dollars and cents—that is leading to a lack of appreciation of the scientific mind. It is commercialism pure and simple that is hindering scientific expansion—a modern commercialism that cannot appreciate the danger in the fact that although science, like virtue (as Kingsley puts it) is its own exceeding great reward; it is liable to die of neglect because of its altruism. What does industry owe to science? What would have been the position of industry today but for science? How much of our present-day comfort and success is due to pure science, how much of our present-day security is due to the work of scientific men? And what could industry have done had it systematically encouraged science during recent years? These are pertinent questions.

Since 1821 the world has been utilizing Michael Faraday's purely scientific discovery in connection with electro-magnetic induction. The primary achievement has been elaborated by experimentation and research to such an extent that it must be admitted that many if not most of the notable electrical inventions would never have resulted but for the science of Faraday. It is to pure science that we owe our major tribute, not to experimentation along commercial lines. For Faraday was prepared to risk so much for pure scientific research that, according to one of his biographers, he gave up the idea of profit because "worldly gains became contemptible in comparison with the rich scientific province he had subdued".

This is the spirit that occasionally gives to the world

a great scientist. But what has been done to perpetuate the ideals of Faraday? One wonders how many others, who have the same view of achievement for achievement's sake, are disheartened at the outset by the demands from utilitarianists for a tangible commercial result from all research, and at every stage of the investigation. And must it not be admitted that, so long as the initiative of scientists is cramped and circumscribed by the dictates of those who have no appreciation of the nature of a scientist or the method of his work, no apprehension of the fact that great truths need diligent search, then so long shall we have to remain content with the building of additional stories on the firm foundations already laid, rather than to plan new edifices ourselves.

A common objection to science is that it lacks definiteness of aim. Scientific research may lead nowhere, one is often told. True; but so may also experimental research along predetermined lines. The point that needs emphasis is that, whereas scientific work may lead nowhere, history has shown that it invariably results in achievement, although often arising from a totally different direction from the one originally planned by the scientist. A scientific investigation may have been unfruitful, but the ground has been covered, for once and all, in a scientific manner; and there has been no waste. Hit-or-miss experimentation, so favored by modern seekers after immediate financial results, may be unfruitful as well as useless; for no consideration of any subject is thorough unless it is tackled in a scientific spirit, and with an entire disregard of the ultimate money-value of the discoveries made. And no record of an investigation is worth while unless it is made by an experienced man, one who has all the facts at his finger-tips. In scientific research one thing may be sought, another found. This is an axiom with the independent investigator, whose one aim is revelation, no matter from what direction.

The time is ripe for a realization of the fact that scientific research cannot profitably be hampered by the restrictions that usually hedge the efforts of those who may be employed to solve great industrial problems. A scientist must be given a free hand and trusted to work out his own salvation in his own particular way. The invariable comment is: "But that is no business proposition." No, it certainly is not. Business and science are irreconcilable. A scientist may be a good business-man and he may be a good so-called 'practical' man, but usually he is neither. An intermediary may, and invariably is needed to, translate and deflect the results of his work into utilitarian channels; but this fact does not make purely scientific research the less necessary.

There is a word—"aggressive"—which is used in England to denote the attitude of a person who commits the first act of hostility or offence. American dictionaries

sustain this interpretation; but in American industry to-day an aggressive manner is a *sine qua non*. The columns of the great dailies are replete with advertisements from self-styled aggressive men who need appointments, and from commercial houses who are on the look-out for employees with the desirable qualification of aggressiveness. In the publication of a large corporation with which I was once connected I read the following warning: "Your advancement is largely in your own hands; it is doubtful whether anyone else is worrying over it." I found that this was literally true; the men who succeeded were those who insisted on a recognition of their qualities. In other words, it is personal aggressiveness that counts. For the individual without it I doubt whether there is any hope of advancement, commensurate with his abilities or efforts, in American industrial or commercial work.

Scientists are not temperamentally aggressive, to use the word in either the American or English sense. Consequently, there will always be a great gulf between industry and science, a gulf that may be bridged but that can never be filled in. A scientist who begins to worry over his prospects of material advancement automatically forfeits the designation. Aggressiveness and science are opposite; and so there is a real danger of the scientist being pushed off the map by the aggressive utilitarian. It is nonsense to point morals from such catch phrases as "the survival of the fittest" or "the elimination of the unnecessary". Industry has taken the funds from the balance which was built up by science; and there is a danger of the account being overdrawn. Science the world needs and must have, but it should not be prostituted to the ideals of undiluted commercialism.

Much of our present-day comfort and so-called civilization is due to the fact that industry has built prosperity on the foundations of disinterested and unpaid effort. Discoveries of great scientists have been utilized to the full, and industry now hopes to duplicate such achievements by means of non-scientific experimentation. The type of men chosen for such work may be gauged from the advertisements constantly appearing in the press. The following is a typical example: "Engineer, recent graduate preferred, to carry out research work." It may be assumed that a recent graduate is preferred because the expenditure will be small; but what can be expected from such a junior when his experience is, obviously, nil, and his outlook narrow and immature? Few men in such a category have the ability to record the results even if discoveries were made; and a wasteful repetition of work occurs.

The reason for the frequent failure of experimentation along definite channels is that commercial considerations force it to take a circumscribed path which must always be in direct line with the particular object sought. Immediate practical results are demanded, monthly or even weekly reports are usually insisted upon, and the immense value of definite although possibly unproductive progress is ignored. It is unfortunate that scientific research is not always undertaken in connection with subjects of more or less vital importance to industry and to

the national advance or protection. But time spent on pure science is not wasted; for the scientific mind must be cultivated, and catholicity of interest is an important factor. Much good can be done by directing research along sensible channels without in any way circumscribing its efforts when work is once commenced.

The need for the co-ordination of science and industry has been much in evidence in connection with many industrial efforts, and several examples can be cited with reference to the metallurgy of gold and silver since the introduction of modern wet processes began to revolutionize precious-metal recovery. With the exhaustion of the majority of the known rich gold deposits in all parts of the world, problems had to be faced and solved as to the economical treatment of low-grade ore. Residues left from the more primitive operations and as the result of inefficient beneficiation became bonanzas with the passage of time. The ounce of gold has cost more and more to produce, largely on account of the increasing amount of rock, at times over 20 tons, which had to be mined, hoisted and hauled, crushed and re-ground, and finally treated by metallurgical or chemico-metallurgical methods in order to win that ounce of gold.

For the greater part of the latter half of the nineteenth century it was well known that gold was soluble in a solution of potassium or sodium cyanide. Some scientific research was done; but because the investigations lacked official encouragement or material assistance the work stopped at the first stage, and little attempt was made to discover or evolve a process for recovering the gold from the cyanide solution after it had been dissolved, or to ascertain if this first step in treatment could be accomplished without prohibitive expense, that is, with weak solutions. A syndicate of engineers, among whom was John Stewart MacArthur, made experiments in 1886 in an effort to discover such a process, and their investigations led to what may be termed one of the notable inventions of the century. In all their tests, however, success was gauged by a consideration as to whether or no actual gold could be produced by the method adopted—the gold had to be laid 'on the table'—and a neglect to appraise the real value of theoretical research resulted in faulty judgment and much delay. Various solvents, of a dilution indicating commercial practicability, were tried on the gold ore; and an evil-smelling gas—sulphuretted hydrogen—was used to precipitate the precious metal from the solutions resulting.

With weak cyanide solutions there was no result—no gold was precipitated—and the experiment was voted a failure. As a matter of fact, however, the first stage of a new process had been completely successful. But practical commercial results were being sought, as they invariably are in all industrial research, and a scientific fact of vast importance passed unnoticed and unrecorded. It was nearly a year later that an accidental discovery was made of the absence of gold in the residue from the original test; and it was then realized that the failure to lay the gold 'on the table' was due to the fact that the precipitant used—the sulphuretted hydrogen gas—was ineffective; and further tests then confirmed the con-

clusion that the gold had been readily dissolved in the first instance by means of a dilute solution—a feasible step from the commercial standpoint.

Had the haste of commercialism been replaced by the thoroughness of science the discovery of the cyanide process would undoubtedly have taken place a year earlier. But for an accident it might have been delayed for a decade or more, with economic consequences impossible to estimate. Patents were issued to MacArthur and his associates in 1888 which indicated the use of zinc-shaving as a precipitant of the gold which had been dissolved in the first stage of the process. These patents marked the complete specifications of a commercially feasible scheme for the treatment of low-grade ores.

With the introduction of the cyanide process came a revolution in the industry. Leaching plants were erected in New Zealand, that cradle of progressiveness, in 1889; and in 1890 in South Africa. In 1897 the cyanide process was mainly responsible for the fact that the world's yearly output of gold had been more than doubled within a decade. Much of the increase was due directly to the introduction of cyaniding, but much was also due to the circumstance that a wider field for the treatment of low-grade ores was presented by the standard method of amalgamation with mercury, followed by a cheap leaching with cyanide solution.

Soon after the introduction of the cyanide process it was found that the dissolved gold obtained by the treatment of the ore could be precipitated by passing the solution through lump charcoal, instead of through zinc-shaving. The charcoal cost practically nothing, and so there was a possibility of reducing considerably the expense of treatment; but the results were found to be unsatisfactory. An enormous amount of charcoal was needed to precipitate a small amount of gold, and the modification was never generally accepted as commercially feasible.

From the chemical point of view the reaction ought never to have happened. Discussions arose as to the cause of the precipitation, but no definite or satisfactory conclusion was reached that was generally acceptable. No scientific analysis or investigation was made; and after casual mention by engineers and college professors the innovation passed into the limbo of the impracticable. The question as to why the gold was precipitated on an apparently inert substance like charcoal was viewed as of academic and scientific interest only, and was soon dismissed as unworthy of further attention by those who were keenly interested in a phase of the process where enormous expenditures were being made for a metallic precipitant which was unrecoverable. Contradictory hypotheses were sporadically advanced from time to time, on which there was no umpire to pass judgment; and a lack of recognition of the value of purely scientific investigation and the obstinate retention of the idea that no theoretical questions were worth considering were together responsible for the postponement for a number of years of an important discovery. Had a trained mind been put in charge of research on the theory of the action—the purely scientific aspect of the question—there is

no doubt that the cause of the precipitation would have been discovered almost at once; and there is also no doubt that the discovery would have immediately pointed a way to the practical utilization of charcoal as a precipitant under certain conditions.

Recently, after all these years, two Australian engineers, in an endeavor to effect a war-time economy, stumbled onto the fact that charcoal is suitable as a precipitant, and will under certain conditions prove an efficient substitute for the expensive metal usually used, by merely grinding it to a powder before use, instead of using it in lump form. The fact that the charcoal is more effective when finely divided gives the clue at once as to the reason for the precipitation—it was a physical rather than a chemical action. This hypothesis in definite form comes after many years of inaction and unnecessary expenditure. Had scientific research been applied to the problem in the first instance the cause of the phenomenon would have been discernible, and then the most efficient manner of utilizing the charcoal for the purpose would have suggested itself. In this instance physical action meant surficial action, and by increasing the surface—by reducing the size of the particles—the result is achieved. Theoretical research would, undoubtedly, have disclosed the conditions under which the adoption of the cheaper precipitant would have been practicable and advantageous.

The function of oxygen or air as an aid in dissolving gold by cyanide solution had been known for many years previous to the introduction of the MacArthur-Forrest cyanide process, the importance of oxygenation in this connection having been emphasized by Faraday in a scientific paper published in 1857. But from the time of the discovery of the cyanide process the profession has floundered along with little or no help from theoretical research. A purely scientific discussion invariably failed to create sustained interest, the connection between pure science and successful industry never having been recognized. A number of individual cyanide engineers spent odd hours in investigation and experiment, but none had the time nor the resources to carry the work to a logical conclusion. Occasional research, so-called, was undertaken by students at universities and schools of mines, but nothing definite resulted, and no complete study of the subject was ever made; no scientist was ever intrusted with the problem.

For nearly thirty years the function of oxygen or air in the various stages of the process (other than in dissolving the gold, and that was learnt from scientists) has remained an unheeded theory and beyond the interest of practical men. Hit-or-miss experimentation in some cases suggested that better results, irrespective of wastage, could be obtained by again adding *more* oxygen before the gold-cyanide solution reached the precipitation boxes; but as to any scientific interpretation of the variable results obtained in the many phases of the work, there was nothing but exasperating indecision. Text-books carefully avoided the question.

Vacuum-filters were introduced at an early date to separate the ground or classified ore from the cyanide

solution that had been used to dissolve the gold; and a definite although unrecognized result of their adoption was the removal, by the abstractive action of the vacuum, of much of the air or oxygen from the solution before precipitation of the gold on zinc-shaving or zinc-dust. No convincing data were produced, however, and nothing was published along lines such as would inevitably have resulted from elementary scientific or theoretical research. The absence of any centralized effort in this direction led to much experimentation. Some plants had vacuum-filters and some had pressure-filters. Practice in some places resulted in good precipitation; in others, bad; there was no accounting for the results one way or the other. Varying efficiency was the outcome of apparently parallel operation; and a considerable amount of waste resulted of gold, solvent, precipitating material, and time. The climax was reached in 1918, that is, thirty years after the introduction of the cyanide process, when a patent was taken out by an American engineer who now claims a monopoly over a phase of operation which has been in regular use since the introduction of vacuum-filters, namely, the abstraction, by means of a vacuum, of air or oxygen from the unprecipitated solutions. The Patent-Office at Washington has, apparently, no technical advisers; and patents are issued whenever a search fails to reveal a prior grant.

Whatever the fault of the Patent-Office, however, it is evident that in the case under consideration the patentee was the first to insist that, by adopting the simple expedient of removing the oxygen or air, the efficiency of the process may be considerably increased; and marked economies of precipitant and solvent will result. In hundreds of plants this had been done unconsciously for many years. In other cases operators were wondering why their results were so erratic, why their costs were so high. In the absence of a sound foundation of fundamental principle the industry has muddled along, avoiding a definite line of research, and content with the empirical results of the unencouraged and unpaid efforts at improvement carried out in odd moments by zealous though inexperienced investigators, whose work was too often condemned by so-called practical men as an effort to 'get into the spotlight'. Had a real scientific investigation been placed in charge of a capable research chemist the industry would have been saved many millions of dollars; and waste, uncertainty, and the unnecessary expenditure of time and money, much of which was altogether unproductive and barren of result, or which merely indicated the duplication of futile effort, would have been avoided.

When there is a clear problem to be solved it is the scientist who is best equipped with knowledge of what has already been done, and who knows the particular line of research that should be undertaken to solve it. It was Humphry Davy, the scientist, who evolved the miners' safety-lamp. It indicates a paucity of intelligence to ignore what is owed to scientists, whose work carries them above the plane of aggressiveness that industry is wont to admire in this age of notoriety. It would be pitiable to belittle or discount the scientific side

of Davy's invention which, above all others, has contributed to the safe working of that essential, coal. When it was suggested that he should patent the safety-lamp he refused, saying that wealth could not increase either his fame or his happiness. This is the scientific spirit.

Another aspect of the matter demands consideration. The decay in pure science and the attitude of disdain that is being taken toward it by industry and commerce is leading to a steady deterioration in the manner of presentation of non-scientific data of vital importance. With an almost entire elimination of pure science from curricula has come a turgidity of exposition that is deplorable. It is the great scientist who teaches us not only how to discover, but also to transmit the acquired knowledge with a clarity and simple beauty of expression that we all enjoy and envy. But this is merely an outward and visible sign of the inward and scientific mind. So long as science remains divorced from the resources and help of industry so long will many great truths remain hidden, and unsung in language befitting the achievement of their discovery. There may be no obvious problems to be solved but that fact constitutes no reason why scientific investigation should be decried. We must admit the verdict that we are no judges; we do not know what scientific research and men of science could do for us if ample opportunities were afforded for investigation. It is becoming more and more evident that the prejudices against pure science prevent us from adding, in an adequate manner, to the reserves of knowledge, other than by adapting to present-day needs the discoveries of the past. Other ground should be scientifically prospected in all directions. Much of the work may be barren of immediate result; but an endeavor should be made to prevent the economic waste that must inevitably occur when reliance on new discoveries is placed on the results of haphazard, hit-or-miss experimentation—often from duplicated effort in rival organizations—carried on without scientific guidance, and with no other object than immediate commercial gain.

A scientist should be considered as a valuable asset to any country, not as an individual of little practical worth, because he is too costly an investment and because he will not, and cannot, guarantee a return for money expended. It should be remembered that true scientific research is never unproductive of good; for one result, at least, is to inculcate a thoroughness of analysis, a breadth of view, and a clarity of deduction that is of inestimable value to the worker, his employer, and the nation.

Achievement along new lines necessitates, as a preliminary the abandonment of the present unreasoning attitude toward pure science; we must reject the idea that experimentation and research must be curtailed or carried out along paths with a pre-determined end in sight. Progress without true scientific research can only be accidental. With it, who knows what the future may have in store? The country that can afford to encourage the scientific mind, and then place its greatest scientists on research work in each phase of industry, with a free hand as to the line of action to be taken, and with ample resources, will find that commercial as well as intellectual

supremacy have been won. For few believe that the world has reached the zenith of great discovery.

Science needs and deserves encouragement, sympathy, and facilities. It must be allowed to work in freedom and without restraint. The provision of funds is not all that is necessary; for discovery is not an open book, to be read by the passer-by. It must be approached by men of keen analytical and dissective minds, men with experience, knowledge, perception, logic, and a capacity for unlimited perseverance. Three essentials are needed: the best men that can be found, ample resources, and patience as to results. If progress is desired, then nothing will be achieved by making research a means of livelihood for mediocrities. The true inquiring scientific spirit must be fostered in the first place, not discouraged as at present, then allowed ample opportunity for development. The greater the utilization of individual ability and keen scientific sense the less the time needed to uncover the hidden truths that the world needs.

The Turnover of Labor

Records show that there are few, if any, industries in which the turnover of labor is so large as in mining and metallurgical operations. Some of the features of the problem are discussed in a recent bulletin of the Federal Board for Vocational Education. Labor turnover is of import to employers chiefly because it costs money to replace separations. Gross separations cannot be depended upon to show the extent of harmful turnover, for the reason that such separations include lay-offs which ordinarily do not have to be replaced. The replaceable separations constitute, therefore, the only practical measurement of the extent of costly turnover.

The extent of labor turnover may be said to be a practical gauge for measuring the relative satisfactoriness of employment policies, general wages, and labor conditions. This is so because, aside from lay-offs, which by their very nature call for no replacement and constitute, therefore, no turnover, the two principal causes of turnover are discharges and voluntary resignations. Practically speaking, the extent of discharges indicates the relative ability of the management to carefully select, train, and manage its help. The relative frequency of resignations indicates in a practical manner the relative satisfactoriness of the labor and wage conditions in the establishment. Wage-earners whose principal source of livelihood is their daily job resign only when they are, for some reason or other, dissatisfied with their work and can, or think they can, obtain better positions. Labor turnover represents a definite, though not easily calculable, economic loss to the employer. The principal items entering into this loss are: (1) the clerical cost incident to firing and replacement; (2) the cost of training newly hired employees; (3) the wastage, breakage, etc., attributable directly to inexperience; (4) the maintenance of idle machinery and equipment while separations are being replaced; (5) the decrease in the general efficiency in the organization due to the constant state of flux in the working force; and

(6) the tendency on the part of new employees to increase the frequency and severity of accidents.

Turnover in an organization does not take place in an equal degree throughout. Some parts, such as, for instance, departments employing large numbers of new employees or casual workers without skill, usually have large turnover; others, employing, for instance, handy men with longer records of service, might have a medium turnover; while still others, such as those concerned with maintenance and employing old skilled mechanics, may be almost stationary.

The methods used in the computation of turnover will vary, of course, with the meaning of the term. If by labor turnover is meant, as in business, the general turnover of men—accessions as well as separations—or the labor flux—the extent of turnover will be measured by the ratio which the aggregate of accessions (hirings and re-hirings) and gross separations (discharges, resignations, deaths, marriages, etc.) will bear to the working force during a certain period, usually one full year. Some employment men see their turnover wholly in accessions or hirings, in which case the turnover is measured by the ratio of accessions to the working force. Others, however, think that gross separations constitute the best method for measuring turnover. In such a case the turnover extent is measured by the ratio of gross separations during the period to the working force. The various policies bearing upon the extent of the labor turnover in the working force may roughly be classified into two main groups: (1) methods of hiring, placement, and discharging, and (2) methods of reducing voluntary separations. The latter group may further be subdivided into: (a) wage policies and wage changes; (b) conditions of employment; and (c) agencies for the adjustment of grievances.

'INDUSTRIAL MEDICINE' is one of the most potent means of promoting efficiency of labor and has application to every branch of mining operations, according to Arthur L. Murray of the U. S. Bureau of Mines. In the selection and planning of camp-sites, the sanitary engineer is indispensable in determining adequate water supplies; methods of drainage including proper disposal of sewage; suitable housing arrangements as regards light, ventilation, and overcrowding; and provisions for the disposal of refuse and waste. In the selection of labor industrial medicine plays an important part. By careful study of working conditions, and the correction of conditions and causes leading to accidents and illness, much needless time loss may be eliminated. Through sanitation applied to mining camps or towns and the safeguarding of the conditions under which employees live, the general health of the community is promoted. Through medical welfare-work, especially by popular instruction in personal and public hygiene, much sickness with its resultant suffering and time loss may be prevented.

DURING the fiscal year ended June 30, 1920, 912,750 gold coins, 128,728,400 silver, and 603,942 minor coins were made by the U. S. Mint.

The Work on Mineral Resources Done by the United States Geological Survey

By EDSON S. BASTIN and H. D. McCASKEY

*The United States Geological Survey has been charged by Congress with many duties, but one of the most important is that of making an inventory of the country's mineral wealth as utilized in the industries. Considered in connection with this duty, the Survey may be described as an accountant whose task it is to know where the valuable mineral deposits of the United States are situated; what, if anything, they are contributing year by year or month by month to the economic life of the country; and, in a general way, what they may be counted upon to contribute in future years.

The mineral investigations of the Geological Survey fall naturally into three major groups. Those of one group, conducted by the division of geology, consist of the study, interpretation, and mapping of the geology of particular districts, of the discovery of mineral deposits, of the determination of their approximate magnitude and their suitability for industrial uses, and of the study of the natural conditions or processes that control their formation or that limit their development or extent. The mineral investigations of a second group, conducted by the division of mineral resources, consist in compiling a continuing statistical record of the mineral production of the country and in reporting new sources of minerals or new methods of their utilization. Within recent years a third group of the mineral investigations of the Geological Survey has consisted in the classification of the public lands with respect to their content of mineral wealth. This work finds immediate application in controlling the conditions under which such lands may be sold, leased, or utilized, but it has increased the knowledge of the country's mineral reserves, especially of those that are little developed or not developed at all.

The year 1918 was the thirty-seventh year of consecutive compilation of mineral statistics by the United States Geological Survey, and many of those who have contributed to the success of this work or have been benefited by it may welcome the following brief story of its development and its scope.

The first annual report of the Geological Survey on the country's mineral resources was that for the year 1882. It was specifically authorized by an act passed at the first session of the Forty-seventh Congress, and it was compiled under instructions issued August 5, 1882, by Maj. J. W. Powell, who had succeeded Clarence King as Director of the Geological Survey. Since then a systematic annual canvass of the mines, quarries, and oil and gas wells of the country has been made by a regularly organized division of the Survey, for many years known

as the 'division of mining statistics and technology', later as the 'division of mining and mineral resources', and in more recent years as the 'division of mineral resources'. The first geologist in charge of the division was Albert Williams, Jr., and he had among his associates Charles G. Yale, in charge of the Pacific division and then editor of the 'Mining and Scientific Press', of San Francisco. Mr. Yale is still in charge of the San Francisco office of the Survey and probably is acquainted with more mining men on the Pacific Coast than any other man. Among other associates was David T. Day, who succeeded Mr. Williams in charge of the work in 1886 and remained as geologist in charge until 1907, when he was succeeded by one of the division staff, Edward W. Parker, who remained statistician in charge until his resignation from the Survey in 1915. Mr. Parker was in turn succeeded by his principal associate, H. D. McCaskey, who relieved him early in 1915 and continued as geologist in charge of the division until January 3, 1919, when he was relieved by Edson S. Bastin, the present geologist in charge. During the 37 years covered by this work, from late in 1882 to the end of 1919, the Survey has had only three directors, namely, J. W. Powell, Charles D. Walcott, and George Otis Smith; and the division has had only the five chiefs named above. This long-continued service has made for continuity of effort and for maintenance of worthy tradition and of esprit de corps, and as each administrative chief has been succeeded by a former associate the whole work has been marked by continuous and consistent growth.

It is interesting to recall, however, that the 'organic act' of the Survey—the act upon which the organization of the Geological Survey was laid out by the first Director, Clarence King, in 1880—provided for investigations of the country's mineral resources, and in the census for that year well-known geologists of the Survey, including S. F. Emmons, George F. Becker, and Raphael Pumpelly, assisted Mr. King in the first systematic statistical investigation of the mineral production of the United States. These men, with Henry Gannett and Whitman Cross, also of the early Survey staff, assisted in compiling the first report of the series now entitled 'Mineral Resources of the United States'.

The Geological Survey has directly and notably aided in the statistical canvass of mines and quarries in the four censuses taken since its organization—those for 1880, 1890, 1900, and 1910—and is now preparing to co-operate in the census for 1920. In the mineral census for 1880, conducted by the Survey at the request of the Census Bureau, the method of obtaining returns directly

*To be published in 'Mineral Resources', 1918. Part I.

from producers was first put into practice in a broad way. Cordial and effective relations with the entire mineral industry were then established by the Survey and have since been continued and widened.

After the statistical work was begun by Mr. Williams and during much of Dr. Day's administration a central staff in the Survey maintained current lists of mineral producers, sent out schedules, and compiled and tabulated the returns received, but many of the chapters were written on a contract or for an honorarium by specialists not on the permanent staff of the Survey and not residing in Washington, who gave only a part of their time to the work. In this way the Survey availed itself of the experience and knowledge of experts like John Birkinbine, as to iron; Charles Kirehoff, as to copper, lead, and zinc; and George F. Kunz, as to gems and precious stones. During the early part of this period, also, when the Survey's central force was small and when it was employing specialists who were engaged principally in other occupations and were not in constant touch with the statistical work, it was not always practicable to make the canvasses as complete as they were made in the first year (1880) and as they were again made in later years; but though some loss was thus suffered, some gain was made by the earlier publication of results.

To keep more closely in touch with the rapidly developing mineral industries and to cover every phase of economic and mining geology it was finally determined to revert to the plan of making a comprehensive and detailed statistical campaign in every mineral industry, similar to that made by the Survey for the census of 1880 but on a much larger scale. It was arranged to develop specialists from the economic geologists and trained engineers and statisticians of the permanent staff of the Survey and to re-establish permanent Western offices. Waldemar Lindgren undertook the reorganization of the work on metals and really became successor to Clarence King in directing the investigation, both geologic and statistical, of the precious metals, of copper, lead, and zinc, and of the rare metals. He organized the Survey's offices in Denver, Salt Lake City, and San Francisco and brought them into close contact with the metal-mining industries, except the iron industry. About this time Mr. Parker succeeded Dr. Day in charge of the mineral statistical work. With the appointment of selected specialists from the Survey staff for every commodity and with several accessions to the trained statistical and clerical staff, the statistical work was made more complete and accurate and was supplemented by field-work done by trained economic geologists. Thus we find the organization today, with some changes in personnel, bringing to its task the strength gained by the continued development of methods and of men and by intimate professional contact with the mining industry during a period of nearly 40 years.

From 1880 to the end of 1918 the value of the mineral production of the United States has increased from \$367,000,000 to more than \$5,500,000,000, nearly 15 times, or, measured in another way, from a little over \$7 per capita to more than \$52. The funds allotted for measuring this

production have increased from \$10,000 in 1890 to \$100,000 in the year 1918-19, or only 10 times. The staff in 1918 numbered 32 technically trained specialists, most of them geologists and mining engineers, of whom 12 devoted their entire time to the mineral statistical work and the remainder devoted some of their time to geologic studies. In addition, 43 stenographers and clerks, many of them highly trained in statistical work, were employed for full time.

As the statistical work has grown in magnitude it has tended to absorb a larger and larger share of the time of specialists who were expected to devote only part of their time to it. Many geologists who have enjoyed the 'touch with the practical' which the work on mineral resources affords have found themselves forced by the growth of the mineral industries to devote their full time to the work and to abandon their chosen scientific labors. This condition has greatly retarded the geologic work of these members of the Survey, who have been unable to finish extensive and important field investigations. Recently a remedy for this condition has been sought in the selection for work on mineral resources of persons willing to devote their entire time to it, and the new grade of 'mineral geographer', established early in 1919, is designed to furnish, through the civil-service system, eligibles for this work.

The field covered by the intimately interlocking activities of the Survey in the investigation of the mineral resources of the United States now includes every known raw mineral product and commodity of economic value and anticipates future development by including some rocks and minerals that are of no present economic value but that may be valuable in the future. The Survey's lists of mineral operators now contain more than 110,000 names and addresses, including operators of mines, quarries, wells, mills, smelters, and refineries, all of whom are in direct touch with the Survey, not only supplying information, but also receiving it. The work has received international recognition as the most complete governmental investigation of mineral industries yet made, and Congress has repeatedly given it approval and the substantial recognition of increased, though still inadequate, funds and facilities.

In all its investigations of mineral resources the Survey has aimed to avoid duplication of work by co-operating as closely as practicable with other Federal bureaus and offices, particularly with those that are doing statistical work or that are especially interested in mineral statistics, such as the bureaus of mines, standards, and foreign and domestic commerce, and the Mint. Many trade-bodies and 18 State organizations also co-operate with the Survey in work on mineral statistics, and co-operation will be extended to other States as rapidly as they make funds or facilities available for their share of the work. The Geological Survey recognizes, too, that a statistical service organized for the benefit of the mineral industries should impose no unnecessary burdens upon those industries and has therefore avoided the unnecessary multiplication of requests for the same data.

At the beginning of the war in Europe in 1914 the

Survey, as it had compiled a mass of data on domestic mineral resources and some on foreign resources, and was in intimate contact with all branches of the mineral industries, was able to furnish the public with much information relating to the raw materials needed to fill orders for war material from Europe. The rapid increase in the number of inquiries made during the War showed the usefulness of the work performed. Little has been published concerning the great and highly diversified war work of the Geological Survey, which extended through many mineral industries and through all the Federal departments, for it has been held throughout the Survey that this work was a privilege not to be cheapened for self-glorification or loudly exploited as an exhibition of patriotism. Now that the War is over, the Survey's work in it may be more freely mentioned, and, in justice to the men who aided in it, an account of it should form a part of every complete record of the participation of the United States in the War.

When the United States entered the War the Survey was immediately called upon to assist the War and Navy departments and many new war boards, especially the Council of National Defense, the War Industries Board, the War Trade Board, the Shipping Board, and the Capital Issues Committee, in their rapidly expanding war activities. With no increase in appropriation and, for most subjects or materials, no increase in technical or clerical staff, the statistics of several mineral resources were collected not annually, as before, but quarterly, monthly, or even weekly. This expansion was made possible only through the complete sacrifice of all the purely scientific work that had before occupied a part of the time of most of the mineral-resources specialists and through longer hours of more strenuous labor by the specialists and clerks.

The Survey furnished rooms and other facilities for mineral committees of the War Industries, War Trade, and Shipping boards and for the interdepartmental Joint Information Board on Minerals and Derivatives, adjacent to its own specialists and records, and thus and in other ways aided the numerous war organizations in finding their way to effective work. By establishing this intimate contact with the organizations that needed information concerning minerals, comparable to its intimate contact for many years with the industries that supply the information, the Survey had a unique opportunity to be of larger use—an opportunity of which it gladly availed itself to the limit of its ability.

The experience gained by the Survey during the War and the growth of the demand for mineral-statistics have shown the need of expanding this work so that it may include the preparation of more detailed and frequent current domestic statistics and more exhaustive research into foreign mineral resources. To adapt the organization to its changing responsibilities the Director of the Survey provided for a larger service, effective at the beginning of 1919. The most noteworthy part of this provision, perhaps, has been the establishment within the division of mineral resources of a section of foreign mineral deposits,

charged with the assembling, mainly from the official reports of foreign governments, of statistics of mineral production, imports, and exports and with the compilation, from both public and private sources, of information showing the location and size of foreign mineral deposits, particularly those that contribute to our own mineral imports or that compete with our mineral exports. The interest and co-operation of some large American companies that are interested in foreign mineral deposits have already been enlisted in this great work, but as only a small fund and personnel are available for its prosecution it has merely been begun. In the work on both foreign and domestic mineral resources the Geological Survey needs the continued and increased support of the public and of Congress that it may go forward confidently to larger and more effective service.

The World's Production of Gold

The United States Geological Survey has given out some preliminary figures showing the production of gold throughout the world in 1919. The production in the United States was \$58,285,196; Canada is reported to have produced \$14,687,000; India \$10,028,000; Australia (not including New Zealand or the Islands), \$29,268,000; the Transvaal, \$171,640,123; Rhodesia and West Africa, \$18,631,070. There was a probably large decrease in the production of gold in Russia and Siberia in 1919. Some increase was probably made in the output of Central America and South America, which, however, was doubtless offset by decreases in the output of other countries. The incomplete returns now available indicate that the world's production of gold in 1919 was between \$345,000,000 and \$350,000,000. The world's production in 1918 amounted to \$380,924,500. The Geological Survey further states that information received during the first six months of 1920 indicates a still further decrease in the production of gold in the United States and that the output for the year will probably be less than \$50,000,000. The production in Alaska, Colorado, California, Oregon, and Montana will be much less in 1920 than it was in 1919, because water is very short for placer mining and many stamp-mills are closed. Canada as a whole may increase its output, although the production of the Yukon districts will be smaller than last year. The output of Russia cannot be estimated. That of Australia will show a decrease. That of South Africa and South America will probably show no radical decrease. According to the Geological Survey, the indications are that the decrease in the world's production of gold in 1920 will not be so great as it was in 1919. [Our estimate of the world's output of gold in 1919 was \$350,044,489, as given in our issue of May 8, 1920.—EDITOR.]

BETWEEN January 1 and March 31, 1920, inclusive, 4899 flasks of quicksilver, each of 75 lb. net, was produced in the United States. This is 852 flasks less than the output in the fourth quarter of 1919 and 1226 flasks less than that in the first quarter of 1919.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

VALUATION OF MINING PROPERTY IN THE STATE.

PHOENIX.—The State Tax Commission has announced the valuation of Arizona mines as \$389,029,919, which is \$25,000,000 less than the valuation for 1919. Five new properties put a half million dollars valuation on the books this year, but the reduced total is due to the large number of small mines which have closed down, owing to the condition of the copper market, and to the fact that many of the large properties were working only at 35 to 60% of full capacity. It is interesting to note from the statement of the Tax Commission that there are at present 43 producing mines in the State of Arizona.

The highest valuation placed on any property was that of the Copper Queen branch of the Phelps Dodge Corporation, which amounted to \$65,394,204, being an increase over the 1919 figures, of nearly two millions. The Inspiration property in the Globe-Miami district was assessed at \$65,372,690, being a reduction of almost eight millions from the 1919 valuation. The Calumet & Arizona Mining Co.'s valuation was increased approximately two millions over last year, while the figures for the United Verde Copper Co., and United Verde Extension Mining Co. show a decrease of \$3,800,000, and \$2,400,000, respectively, from the 1919 assessment.

BISBEE.—It is anticipated that the new 4000-ton mill for handling the concentrating ore of Sacramento hill will be completed early next year. Rapid progress has been made in removal of waste capping over the orebodies and it is estimated that when production commences, early in 1921, approximately 6,167,000 cu. yd. will have been removed; 71% of the waste stripping necessary before ore production starts was complete at the end of last April.

The ventilating shaft, being sunk by the Calumet & Arizona Mining Co. below its Briggs shaft, is going down at a remarkable rate. The log during the last week showed an average of 10 ft. per day or 70 ft. for the week. The shaft has now reached a depth of approximately 385 ft. An aftermath of the 'Bisbee Deportation' cases was the recent issuance of summons from the Superior Court at Tombstone in 37 civil cases, complaints in which were filed a year ago, and which arose from the deportation of July 1917. With the issuance of these summons there are now more than 500 civil cases pending, the amounts claimed for damages ranging from \$10,000 to \$75,000. Taking \$25,000 as an average claim, the total amount

claimed would be in the neighborhood of \$12,500,000. The defendants in the last 37 cases filed include all the large mining companies in the Bisbee-Warren district, as well as a number of prominent citizens.

JEROME.—As previously announced, the plant of the Jerome-Superior Copper Co., near the Hopewell tunnel, is being electrified throughout. This means the installation of thousands of dollars worth of new machinery and the removal of much of the present steam plant. There are at present 57 men on the payroll, not including the electrician and crew of five men imported from Prescott who will do the electrical work under contract. The depth of the shaft is approximately 860 ft. and steady progress is being made in sinking, despite the great volume of water. Quartz porphyry is the formation in which the shaft is bottomed. It is the present intention to sink to a depth of at least 1000 ft. before doing any more lateral work, and if indications are not satisfactory at that level sinking will continue as the plant is capable of carrying the shaft down to 2000 ft. if necessary. The pumps are lifting an average of 160,000 gal. every 24 hours. The flow is steadily increasing as the shaft gains depth, due no doubt to the big sheared zone. A big pump for installation on the 1000-ft. level, or above, if needed, is already on the ground. Machinery for a water-softening and cooling plant is at Clarkdale and will be hauled out to the Jerome-Superior at once. This plant will take most of the lime out of the water and thus greatly improve it for domestic and other purposes.

The latest report from the Shea Copper Co. advises that the tunnel has attained a length of slightly more than 100 ft., and that work is progressing favorably. The tunnel is now 280 ft. from the shaft and a raise will be started at once, in order to cut the orebody.

One of the most spectacular fires ever seen in the Jerome district, occurred the latter part of this week when the old coke-bins of the United Verde Copper Co. were destroyed by fire, supposedly caused by cinders from a passing engine. Simultaneously the pipe, leading from the oil-tanks opposite the bins, broke and some 5000 gal. of fuel-oil added to the fire. No. 3 power-house stands close to the site of the bins and this structure was in serious danger more than once, but was saved by good work on the part of the mine fire-fighting crew.

H. P. Henderson, consulting engineer for the Jerome-Verde Co. recently issued a report on conditions at the mine in which the necessity for re-financing the company is urged. It is recommended that development work be

continued on the 1200-ft. level of the Main Top orebody, which has already produced over \$157,000. Under date of March 12 a report was submitted to stockholders calling attention to the condition of the mine, the desirability of continued development, the financial condition of the company, and the immediate need of additional operating funds. Mr. Henderson advises that "complete cessation of operations would result in much damage through flooding of the workings and caving. Therefore to ensure the continuance of operations and to safeguard their own interests, the stockholders must act without delay".

SUPERIOR.—A road is being constructed between Superior and Miami, the completion of which will shorten the distance between Phoenix and Miami by about 25 miles. One of the novel features will be the driving of two tunnels, one 240 ft. in length, and the other 270 ft. Work will be commenced from both ends of each tunnel, thus providing labor for four crews. In certain sections the cost will approximate \$250,000 per mile, on account of the heavy construction.

COLORADO

CANADIAN SYNDICATE TO OPERATE AT IDAHO SPRINGS.

IDAHO SPRINGS.—A Canadian syndicate has taken over the Gem and Silver Age mines in Clear Creek. Re-timbering of the Gem shaft has commenced and equipment ordered. The development will start on the Silver Age. Ben McDougal is in charge of operations with R. B. Lamb as consulting engineer. W. E. Renshaw of Idaho Springs is president of the mining syndicate, Sir Henry M. Pollatt of Toronto, president of the Mining Corporation of Canada, is chairman of the board of directors.

ASPEN.—Unwatering of the Smuggler mine by air-lifts is progressing and a gain of three feet daily is reported. More lifts will be used when additional power is secured. As levels are recovered the ground will be operated either by the leasing company or by sub-lessees. All levels down to the ninth are said to have silver-lead ore exposed that will pay well at present prices. Other properties on Smuggler mountain will become active when the Smuggler is unwatered.

SILVERTON.—The Martin Mining & Power Co. is preparing to resume on its properties the Golden Fleece, Gold Lion, Jennie R., and Tom Moore in the Picayune basin near Eureka in the San Juan. Samuel G. Martin of New York, formerly of Aspen, is now in Denver purchasing machinery and equipment.

BRECKENRIDGE.—G. W. Morgan lessee of the Brooks-Snyder on Shock hill has opened up a vein containing six inches of chloride ore sampling between 300 and 400 oz. silver per ton. A sacked shipment will be sent forward to the A. V. smelter at Leadville, this week. The Quandry Queen is shipping high-grade silver-lead ore. Three feet of the six-foot vein has a high silver content. Wellington Mines continues shipping zinc concentrate and last week loaded out four cars of lead concentrate, the first lead shipped for several months. The company, like others, is working short-handed.

The Dianthia property has been taken under lease and a cross-cut tunnel has been started to cut the vein below the present workings that, when operated last year, produced light tonnage of high-grade ore.

An electric hoist has been installed at the Deep shaft, Shock hill, and power will be turned on by the Colorado Power Co. as soon as the power-line can be connected. A pumping plant, electrically operated, will also be installed. Water is standing at the 300-ft. level, where work will start.

LEADVILLE.—The Penrose shaft of the Down Town Mines continues heavy production of silver-iron ore and lead carbonate to the Pueblo and Durango smelters and zinc carbonate to the Western Zinc Oxide Co.'s Leadville plant. Improvements to the District mill are progressing. New machinery is being installed and ore handling facilities added. The mill will treat ore from the C. and G. lease, of which John Cortellini is manager, and it is estimated the lease will keep the mill running at a capacity of 150 tons per day.

BOULDER.—The Keystone mill is again in operation and stopes and dumps at the Keystone mine have thus far furnished ore for tests, in which flotation is first used in the treatment, while concentration later is used on the tailing and slime. Preliminary runs are reported to show greatly increased saving but the light gold content in the Keystone ore, it is said, has so far not been recovered.

MICHIGAN

FRANKLIN COMPANY LEVIES ASSESSMENT.

HOUGHTON.—Production in refined copper by the Calumet & Hecla mines shows an increase for June of 219,068 lb. The output for June follows: Calumet & Hecla, 5,097,594; Ahmeek, 1,773,200; Isle Royale, 878,508; Allouez, 333,800; Osceola, 661,500; Centennial, 86,000; White Pine, 160,077; Superior, 32,000; total, 9,022,877. The May production for Calumet was 4,920,786; Ahmeek, 1,652,900; Isle Royale, 851,200; Allouez, 367,100; Osceola, 739,500; Centennial, 65,100; White Pine, 184,625; LaSalle, 22,600; total, 8,803,811. The production of Calumet in June included 1,279,491 lb. of copper recovered by the reclamation-plant. Calumet & Hecla has begun work on an order for 1500 tons of copper for France and a consignment of 500 tons left here recently for Montreal for trans-shipment to European markets. A steamer is expected this week and will take out 1600 tons for Eastern markets, chiefly Buffalo. The metal for France is special-order copper, consisting of billets and wire bars.

The Franklin Mining Co. announces that financial and operating conditions compel the calling of an assessment of \$2 per share, due August 12 by shareholders of record August 11. The company's announcement says: "The mine must be kept free of water and the plant in condition to resume operations because the recent underground developments warrant the resumption of production as soon as normal conditions again prevail in the copper industry. Our bankers say the cost of this should be car-

ried by stockholders, which cannot well be denied. Developments since the first of the year have proved a long stretch (650 ft.) of good ground at the bottom of the 39th level on the Pewabic amygdaloid. It is undoubtedly better than any similar ground heretofore opened. There are excellent reasons for the belief that the ore will continue and probably improve as drifting proceeds north. This theory is corroborated by the fact that the 30th level is better at 1600 ft. than it is at 600. It costs but little more to continue this development at the bottom of the mine than it does simply to provide for the absolutely necessary pumping; consequently, development there should proceed while the price of copper is low, as every foot of new ground opened will be a big asset when production is resumed."

Mayflower-Old Colony has opened a good quality of ground in its south drift since the work was resumed in this direction. The raise in the west cross-cut also has started and is breasted in trap formation. There is a hope that this opening will encounter the Mayflower lode as it proceeds upward and, in this event, the development of the vein will be possible with less difficulty. To the north, the cross-cut continues in the conglomerate lode, the same formation that was entered by the cross-cut 140 ft. farther west, and 320 ft. from the shaft. Altogether Mayflower has close to 1000 ft. of openings on the 1700-ft. level and it may be that an equal amount of exploration will be necessary before the work on this level is complete.

The employees of Allouez and Centennial have been absorbed by Ahmeek and Kearsarge, principally, while a few have been given positions in the Calumet conglomerate and at the C. & H. mills. The result will be an increase in tonnage for Ahmeek, Kearsarge, and Calumet proper, in July or until the two mines resume. Both mines are maintaining substantial crews for repair work, so when the time comes to re-open there will be no delay. The Calumet & Hecla company reports that from 20 to 25 former employees are returning each week from the automobile manufacturing centres, and whenever possible they are being given their old positions. Other workmen also are finding their way north, so the mines are gaining slightly in man-power. To offset the number who are returning, other miners and trammers who own farms are going back to complete the harvest, but in the fall they will return to the mines. In connection with the efforts of the mining companies to hold their workers, no operator, perhaps, has introduced such successful methods as Calumet & Hecla. Among other innovations, the company this year plowed and harrowed three immense tracts of land and turned them over to employees without cost to them. Practically every inch of the ground has been converted into garden space and at any hour of the day hundreds of men, women, and children can be seen at work on their miniature farms. The result will be a considerable saving to the employees, for many of them market the products that are in excess of what they require for themselves.

Calumet is speeding up the dismantling of the old

Tamarack mill and as soon as the site is cleared, the erection of the leaching-plant will begin. At the Tamarack mine No. 3 hoist still is being dismantled and as rapidly as the parts arrive at Isle Royale the machinery is being set up in No. 5 engine-house. A delay has been noted in the shipment of steel for the addition to the Calumet flotation-plant, but delivery is expected before the end of the month.

No. 4 shaft, Wolverine, has been re-opened after a suspension of about 20 days, and shipments are divided

A PACK-TRAIN GOING TO SILVERTON, COLORADO

between this and No. 3 shaft. The Wolverine rock is still stamped in the Mohawk mill, however, with about 1½ heads allotted to Wolverine. In the meantime the bins in the Wolverine mill are being overhauled. The suspension of work in the shaft was necessary in order to remove the old concrete supports and install timber, on the 26th, 27th, and 28th levels. In practically every mine on the lake, concrete pillars are being discarded and there is little likelihood that anything other than timber ever will be used again. The concrete experiment has cost the Lake Superior mines hundreds of thousands of dollars, but practically every mine manager has been convinced that a cement composition cannot withstand the constant shifting of the ground. With every earth movement the concrete cracks or crumbles and unless it is removed at once it invariably becomes a menace to the safety of the employees.

MONTANA

GOLDSMITH MINE IS PRODUCING.

WICKES.—The Mount Washington mine is again shipping ore. Work on the mill has been delayed by the difficulty in getting the needed material.

WALKERVILLE.—The Crystal Copper Co. operating the Goldsmith mine is now shipping 100 tons of silver-gold ore per week; 50 men are employed. The ore is from development work on the 500-ft. level and from stopes on the 600-ft. level. New ore-bins have been constructed. A railroad spur has been extended to the property to eliminate the use of haulage by team. M. W. Anderson is in charge.

BUTTE.—Butte & Superior produced during June 8,250,000 lb. of zinc concentrate compared with 5,900,000 lb. for the month of May. North Butte produced 1,616,822 lb. of copper in June. Indications for July are that the 2,000,000-lb. mark will be exceeded. Development work continues to centralize on the Edith May vein on the 3600-ft. level. Cross-cutting toward this orebody is well under way.

TOWNSEND.—A 2000-ft. development tunnel has been completed at the Iron Mask mine in search of a high-grade lead orebody. A 100-ft. drift is now being driven at an angle to this tunnel which it is expected will cut the mineral zone.

COOKE CITY.—Work on the road to Gardiner is well under way with a crew of 10 men and engineers. It is planned to finish some rock construction at the Gardiner end of the highway during the coming winter.

HELENA.—Messrs. Johnson, Gerald, and Weisner have taken a lease on the Sunset mine in the Lump Gulch district. Pay-ore is expected at a depth of 100 ft. where 45 ft. of cross-cutting to the south should reach the main vein. Surface work has indicated rich silver ore.

NEVADA

TONOPAH-BELMONT WILL RE-TREAT TAILING AT MILLERS.

BEOWAWE.—Machinery and supplies are being hauled to the Cortez, on the Lander-Eureka county line, 35 miles south of here. The Arctic, or lower tunnel, 3000 ft. distant and 300 ft. lower than the 3700-ft. Garrison, or main tunnel of the old workings, has been put in condition for continuing it 600 to 800 ft. The present length is 1400 ft. All of the old machinery at the mine is worthless and an entire new plant has been bought. The Arctic is a double-tracked cross-cut tunnel and by continuing it the extension of ore in a winze from the Garrison tunnel can be opened. Practically all of the ore in the mine is in this winze. It is estimated that 75,000 ft. of work, exclusive of stoping, was done in the Garrison, Premium, Fitzgerald, and Arctic claims by the former owners. These claims were developed by raises from the main-tunnel level. The ore contains gold, silver, and lead. The gold is native or is associated with iron pyrite, the lead is found as galena and the silver is in the form of horn-silver or silver glance. The ore in the winze and in the

dumps is estimated to have a recoverable value of \$1,737,000.

SUNSHINE.—Gold-silver-copper ore is being shipped from the Sunshine district, 17 miles south of Winnemucca, by the Sunshine Mines Co. The ore is in fissure veins in limestone that contain silver sulphide in quartz. A tunnel is being driven with power-drills to cut these veins under the present workings.

VIRGINIA CITY.—Seams of quartz 6 in. to 3 ft. wide and assaying as high as \$12 are being cut in a 400-ft. cross-cut from the 550-ft. shaft of the Comstock Silver, operating on the Brunswick lode in the south-eastern part of the district. The company owns four claims and has a lease on adjoining ground. The objective of the cross-cut is the Occidental fissure, in which little work has been done. The same management is to start work on the Comstock Phoenix, in the Sixmile canyon part of the district. The Comstock Phoenix has produced \$400,000 to the 550-ft. level. The shaft is 550 ft. deep and a winze from the bottom level reaches 800 ft. The company will re-open and prospect further from the bottom of the winze and will continue sinking to 1200 feet.

TONOPAH.—The Belmont mill at Millers is to be re-opened to re-treat the tailing. The plant has been closed for more than five years, or since the mill of the company in Tonopah was started. It is reported that a process has been devised by Albert Siler, metallurgist for the company, by which the material can be treated at a profit. It is understood that the Tonopah Mining Co. made an unsuccessful attempt to treat the tailing at the Millers plant of that company before it was closed three years ago.

AUSTIN.—Hubert W. Rast is preparing to start shipping ochre from a mine owned by him near Walters station on the Nevada Central railroad. Rast says a San Francisco paint company has closed a contract with him, agreeing to pay \$35 per ton f.o.b. Walters station.

OSCEOLA.—Silver-lead ore richer than the low-grade material found heretofore has been opened in a raise from a 145-ft. cross-cut on the 100-ft. level of the Lucky Boy, near Osceola, 46 miles south-east of Ely. There is enough ore in the shaft workings and a 350-ft. tunnel, with 700 tons of \$20 ore on the dump, to justify the erection of a 100-ton concentrator, and a plant is now being built. The mine machinery includes a hoist that can lift from 400 ft. and an air-compressor. The ore in the raise is a sulphide in a granite pegmatite vein.

BLACK MOUNTAIN.—Ore assaying \$75 in silver and lead has been found 30 ft. from the portal of a tunnel being driven by the Black Mountain Silver Mining Co. in the Marietta district, 12 miles west of Belleville, in the south-western part of Mineral county. A shallow shaft was sunk in the Black vein, 20 ft. wide, and a 1-ft. seam of ore assaying 150 to 200 oz. silver and 20% lead was opened. The tunnel will cut this vein at a depth of 140 feet.

MONTEZUMA.—The Montezuma Silver Mines Corporation has announced that the 400-ft. inclined Arizona shaft is to be sunk to 1000 ft. A 34-hp. hoist and a 36-ft. head-frame have been ordered for this work. Ore assaying

\$250 in silver, lead, and copper is being sacked for shipment from a 4 to 10-in. seam on the 400-ft. level. A 30-in. width assaying \$16 to \$35 also is being stoped on this level and a carload shipment of both grades is to be made. The rich ore contains 12 to 14% copper, \$6 to \$9 in gold, and 4% zinc. Sinking of the 245-ft. Caracas shaft, $1\frac{1}{4}$ miles from the Arizona, is to be resumed. Work is to be started after an idleness of many years by the Washington Montezuma. This company has a 220-ft. shaft on the claims.

GOLDFIELD.—The agreement for the organization of the Deep Mines has been ratified by all of the companies involved. Contrary to widely circulated reports, the pro-

posed increases in rates for power furnished by the Utah Power & Light Co. to most of the corporations in the State, including the mining companies. The Utah Power & Light Co. was organized in 1912, and D. C. Jackling was elected president, holding that office until January 1, 1920, when he resigned. Lafayette Hanchett, formerly general manager for the Boston Consolidated Mining Co., which company was taken over by the Utah Copper Co. in February 1910 was elected as successor to Mr. Jackling. When the Power company was organized, it took over a number of plants in Utah, Idaho, and Colorado, and acquired several hydro-electric plant sites in

THE ANACONDA COMPANY'S COMPRESSOR-PLANT AND VARIOUS MINES ON ANACONDA HILL

posed shaft of the Deep Mines has not been started and, except that it will be on or near the Blue Bull claims, so far as known a location for the shaft has not been selected. J. B. Humphrey and O. K. Reed, cattlemen, and others are buying supplies to be used in sinking a shaft near the Five to One tunnel. Humphrey and Reed have offered to invest \$10,000 in the Five to One, but their offer was rejected, as the company has ample funds to continue work. The tunnel is now nearly 500 ft. long. Ore $3\frac{1}{2}$ ft. wide, containing some gold, has been found by cross-cutting 60 ft. into the foot-wall of the vein in the Red Hill lease on the Florence. The find was made a short distance below the 400-ft. level. This is the only shoot of high-grade ore exposed in the Florence at the present time.

UTAH

MINING COMPANIES OPPOSE INCREASE IN POWER-RATES.

SALT LAKE CITY.—Hearings have been conducted by the Public Utilities Commission of Utah in the matter of

those States. The company entered into long-time agreements for power service with practically all of the largest industries in this State. As a result of these agreements, several of the largest mining companies, it is alleged, discontinued operation of their own plants, or relinquished opportunities that they had to acquire sites for hydro-electric plants. Owing to the mounting costs of labor and supplies, officials and attorneys of the Power company claim that 60% of their power is being sold, at the present time, for less than the cost of production. The mining companies and other industries are opposing the proposed heavy increased rates, on the ground that the Public Utilities Commission cannot abrogate contracts entered into in good faith, and several of the largest companies are preparing plans for power-plants of their own. Some of the largest increases proposed for mining companies holding special contracts are as follows, the figures given being the amounts paid for power in 1919, and what the contemplated rates, for the same period, would have been: Spring Canyon Coal Co., \$17,000 to \$33,000; Chief

Consolidated Mining Co., \$69,000 to \$107,000; Judge Mining & Smelting Co., \$48,000 to \$93,000; Silver King Coalition Mines Co., \$38,000 to \$83,000; Silver King Consolidated Mining Co., \$10,000 to \$17,000; Utah Consolidated Mining Co., \$41,000 to \$76,000; Utah Copper Co., \$667,000 to \$1,515,000; American Smelting & Refining Co., \$29,000 to \$44,000; United States Smelting Co., \$52,000 to \$116,000. On July 30, attorneys of both sides filed written briefs with the Commission and commenced oral arguments.

There is at present a great scarcity of metal miners in the State, according to Carl A. Allen of the State Industrial Commission. Mr. Allen believes that many metal miners have heard the call of the coal mines, especially those of the Middle West, which are offering better wages than those paid in the local metal mines. At the present time Mr. Allen believes that many former metal miners are hiring out as harvest hands, as many of the men consider that the time spent in the fields is in the nature of a vacation.

PARK CITY.—Ore shipments from this camp for the week ending July 17 totalled 2267 tons, as compared with 2094 tons for the previous week. There are now eight regular shippers. The Ontario shipped 725 tons; Judge M. & S., 432 tons; Silver King Coalition, 337 tons; Daly West, 241 tons; Daly Mining, 101 tons; Naildriver, 115 tons, and the Keystone, 110 tons. The Judge smelter shipped 206 tons of premium spelter during the week.

Directors of the Glenallen property have levied an assessment of one cent per share. For the past few weeks, development work at the property has been at a standstill, and in order to secure the additional machinery to equip the mill, it was necessary to levy the assessment. James B. Allen states that there is considerable ore awaiting the completion of the mill. On account of the high-zinc content of the ore from this property, it does not pay to ship direct to the smelter, notwithstanding the high silver-lead content. The work of driving the Spiro tunnel is going ahead at a good rate, two shifts per day now being employed. The raise in the tunnel is reported to be advanced 50 ft., with indications that ore will soon be cut. The face of the tunnel is now in more than 12,000 ft. from the portal.

Conditions at the Ontario mine are promising, according to Clarence Bamberger, one of the officials of the company. The mine has been entirely re-equipped with electrical facilities and all of the old steam equipment has been abandoned. For the first time in more than twenty years, the 2000-ft. level has been opened and development work of importance will be undertaken. An inside electric hoist and a large skip has been installed for this work. The level has been opened for 400 ft. on the west side and 350 ft. on the east side, the object of the development work being to find good shoots of silver ore cut on the 1700 and 1800-ft. levels. The ore-shoot recently entered by a drift on the 1800-ft. level carries from 40 to 60 oz. of silver per ton. It has been developed on both sides of the 1800-ft. level and the full floor of the drift is in this class of material.

EUREKA.—Work on the new concentrator of the Tintie Standard company is progressing rapidly, and the buildings themselves will be completed soon after August 1. The setting of the machinery will then be started and the first section will be ready for operation before winter. Shipments from this district for the week ending July 17 totalled 136 cars, as against 81 cars for the week previous. The Chief Consolidated shipped 36 cars; Tintie Standard, 30; Eagle & Blue Bell, 10; Grand Central, 9; Dragon Con., 8; Iron King, 7; Victoria, 7; Centennial Eureka, 6; Mammoth, 6; Iron Blossom, 6; Gemini, 3; Tintie Drain Tunnel, 2; Colorado, 2; Bullion Beck, 2; Gold Chain, 1; Swansea Con., 1. At a meeting of the directors of the Pinion Queen Mining Co., E. J. Raddatz was elected president, to succeed Thomas F. Pierpont, who resigned. Development at this property is going along smoothly and the contractors are still using two shifts in sinking. The shaft now has a depth of about 700 ft., and sinking will continue until the 1000-ft. level is reached, unless the formation at some place between those levels justifies lateral development.

The Tintie drain-tunnel, which is being driven for the purpose of draining the district, is now in a distance of nearly 7000 ft., and there is no intention of stopping the work until the project is completed. A force of miners is now engaged in driving a raise to the surface for the purpose of giving better ventilation, this raise being started at a point about 6000 ft. from the portal. After a delay of thirty days, work of sinking the Central Standard shaft has been resumed. A large sump has just been completed on the 400-ft. level and John Taylor, manager, believes that trouble from water is now ended for all time. Two shifts are now being employed in the shaft-sinking, and excellent progress is being made. The formation which the shaft is cutting is highly mineralized, and it is the intention to continue sinking to the 700-ft. level, when drifts will be sent out.

Conditions in the headings, which are being driven in the upper workings of the Uncle Sam and May Day mines, are promising, according to George H. Dern, general manager.

BRITISH COLUMBIA

OUTPUT FOR THE YEAR 1919

VICTORIA.—The monetary value of the mineral output of British Columbia for the year 1919 was \$33,296,313, as compared with \$41,782,474 for 1918 as shown by the official figures given in the annual report of the Minister of Mines. The comparison is shown in the following table:

	1918		1919	
	Quantity Oz.	Value	Quantity Oz.	Value
Gold, placer	16,000	\$320,000	14,325	\$286,500
Gold, lode	164,674	3,403,812	152,426	3,150,645
Silver	3,498,172	3,215,870	3,403,119	3,592,873
	Lb.		Lb.	
Lead	43,899,661	2,928,107	39,475,968	1,526,855
Copper	61,483,754	15,143,449	43,459,339	7,939,896
Zinc	41,772,916	2,899,040	56,737,651	3,540,429

One interesting feature of the above is the increase shown in silver production, reflecting the increase quota-

tions for the metal and, to some extent, the opening up of promising northern fields.

STEWART.—A strong vein of a good grade of ore is said to have been struck on the Unicorn group, and ore of high grade has been brought into Stewart from the Glacier Creek property. An open cut, driven 20 ft. on the latter, has exposed rock containing galena and iron sulphide.

VANCOUVER.—During the War the Consolidated Mining & Smelting Co. started the production of zinc on a large scale. Now, with an annual output of 20,000 tons of this metal and the total annual requirements of Canada not exceeding 10,000 tons, some profitable means of disposing of the excess must be found. The Vancouver board of trade promised its assistance in the solution of this problem.

NELSON.—Four of the levels of the Blue Bell mine are being unwatered by a pump just installed and constructed at the Nelson Iron Works from drawings furnished by S. S. Fowler, manager for the New Canadian Metal Co. As soon as this is accomplished the levels will be actively mined. Last year the Blue Bell shipped to the Trail smelter 1249 tons of crude ore and 36 tons of concentrate. To date the property is credited with shipments aggregating 730 tons.

PRINCETON.—The Princeton Mining & Development Co. is proceeding with the work of placing its mine property, situated five miles east of Princeton on the

Falls by tapping the line to the Copper Mountain mine of the Canada Copper Co.

The annual report of the Canada Copper Co. shows that, with a share capital of \$5,441,046 and a bonded indebtedness of \$2,920,650 there was a dividend distribution of \$622,518 for the year 1919, as compared with \$3,025,347 in 1918. The company invested in nineteen properties in British Columbia last year. Both the

A PROSPECTOR IN MEXICO

Greenwood smelter and the Motherlode mine have been dismantled. On construction at the Copper Mountain mine and the concentrating mill at Allenby \$1,112,000 was expended. Work on the mill and the railway to the mine is making good headway. It was held up by labor trouble, otherwise it is likely that 2000 tons of ore per day now would be coming from the mine. The ore will concentrate to a 25% copper content and the concentrate will be shipped to Trail to be refined.

TRAIL.—An explosion of gas soon after the blast was turned on in re-starting the copper blast-furnace at the Consolidated M. & S. plant caused damage that will delay the starting of the plant for a week or ten days. Ore shipments received during the week ended July 14 totalled 4810 tons, of which 3533 tons came from the Consolidated company's mines. The other shippers were: Blue Bell, Riondel, 123 tons; Electric Point, Washington, 31 tons; Josie, Rossland, 119 tons; Mandy, Le Pas, Manitoba, 822 tons; North Star, Kimberley, 137 tons; and Providence, Greenwood, 35 tons.

PART OF SONORA, MEXICO

Great Northern railway, on a permanent shipping basis. There are three full claims on which the vein has been opened by three tunnels, varying in depth from 48 to 480 ft. The vein is reported to have been traced for about 4500 ft. on the surface and the operators assert that they have a large body of concentrating ore averaging 4% in copper and 1 oz. in silver. A three-drill compressor run by steam is in use and another is to be installed to be run by electric power which will be secured from Bonnington

ONTARIO

LA ROSE CONSOLIDATED SUES TO RECOVER FOR TAILING FROM CUSTOM ORE.

COBALT.—Announcement is made that an order in council has been passed by the Ontario government, authorizing the opening of timber on the Gillies Limit for prospecting, the date set being July 20. The Gillies Limit lies immediately adjacent to the silver-bearing area of Cobalt, and is regarded as being a fairly promising prospective field. During the second quarter of 1920, the Bailey mill, formerly known as the Northern Customs

Concentrator, earned \$50,478. Work was also started on the Bailey mine, and has resulted in adding to the reserve of 20-oz. ore, formerly estimated at 23,000 tons. This ore will be shipped to the mill just as soon as a railway siding can be constructed.

The La Rose Consolidated has entered action against the Mining Corporation of Canada to recover for the value left in tailing from La Rose ore formerly treated in the mill of the Mining Corporation previously operated as a custom plant. The tailing from custom ore treated as well as tailing from ore subsequently treated by the Mining Corporation are all in one common heap which is now being re-treated. The case promises to be decidedly complicated. Production at the McKinley-Darragh is being maintained at from 55,000 to 60,000 oz. of silver monthly. Considerable new ore is being opened, although not at a rate equalling the amount being mined. Negotiations between the Mining Corporation and the Penn-Canadian Mines have terminated unsuccessfully in connection with the proposed purchase of the Penn-Canadian tailing pile of 125,000 tons. The decline in quotations for silver had an important bearing on the failure of the deal. The Canadian Light Railway Construction Co. has announced that 20 miles of the survey for the proposed narrow-gauge railway from Elk Lake to Gowganda has been completed, and that it is now possible to estimate the cost of construction. In order to finance the building of the Elk Lake-Gowganda line as well as a line from Swastika to Larder Lake by way of Kirkland Lake, an endeavor is being made to raise \$1,500,000.

Harry Mills, Minister of Mines for Ontario, announces that during the coming winter courses of training for prospectors will be opened at several mining centres in Northern Ontario, including Sudbury, Haileybury, Timmins, Swastika, and some point at the head of the Great Lakes. The courses, which will be free, will last for six weeks, during which instruction will be given by competent geologists as to rock formation and the sampling and testing of ores. The Department will also open an assay-office at Kirkland Lake, where assays of ore will be made at cost.

PORCUPINE.—The annual report of the Davidson covering the 10-month period from September 1, 1919, to June 30, shows that \$144,245 has been expended in development work, the most important item of which was the extension of the west drift at the 500-ft. level which has been driven along the main vein for 615 ft. This orebody is increasing in width and has an average width of 20 ft. over the entire distance. A gold production of \$17,069 was obtained from the milling of test runs on development ore. The management proposes to sink a large shaft to cut the orebody at a depth of 1000 ft. In the meantime operations at the mine will be discontinued, pending plans for financing the work on a large scale.

The option held by the Dome Mines on the Dome Extension expires September 15, and the question as to whether it will be exercised or not is expected to be determined by the result of work now being carried on at the 10th level. Diamond-drilling has indicated a large

orebody at a vertical depth of 1150 ft. at the boundary line of the two properties having a dip onto the Dome Extension and work is now being undertaken to verify this conclusion. The core from the diamond-drill hole was officially stated to show a gold content of \$7.94 for a distance of 93 ft. and \$5.16 for an additional distance of 23 ft. The McIntyre has declared an interim dividend of 5%, making the third to be paid this year. The total disbursements of the company amount to \$1,985,655 or 55% of the issued capital.

KIRKLAND LAKE.—The main shaft at the Kirkland Lake mine has reached a depth of 900 ft. being 300 ft. deeper than any other workings in the camp. Ore has been proved to occur down to the 700-ft. level. During May the production was valued at \$36,236, the mill-heads averaging \$12.03. Ore taken from a test-pit six feet deep, sunk on the recently discovered vein on the Wood-Kirkland, is stated to yield high assays and to contain gold tellurides.

MEXICO

A NEW RAILROAD PROJECT.

SONORA.—The demands for increased pay made by the Mexican labor unions in the State of Sonora have been carried to such an extreme, that, according to reports from that State, the Democrata mine at Cananea will close down at the end of the month owing to inability to meet the demands of the union. The Cananea Consolidated Copper Co., the big producer of the district, while not acceding to the demands of the union, will continue operations, pending negotiations with the Mexican government. The Mexican copper producers, in addition to being affected by the present condition of the copper market, are subjected to much heavier expenses than American operators, as, in addition to taxes paid to the Mexican government, an export tax of approximately two cents per pound is levied on copper bullion and a heavy import duty on coal and fuel-oils.

It is reported that a concession has recently been granted by the new Mexican government to railroad promoters of Ajo, Arizona, for the construction of a railroad from the Mexican line in Sonora to San Jorge bay, on the Gulf of California. This proposed railroad will start at Ajo, connecting at Ajo with the line from Gila Bend, which in turn connects with the Southern Pacific. It is understood that a survey of the proposed road will be made in the near future. Many years ago a railroad from Tucson to Port Lobos, on the Gulf of California, was projected by the late Frank Murphy, prominent mining man of Prescott, but it was never constructed. San Jorge, where the new proposed railroad expects to build its terminal, is believed to be a more advantageous point than Port Lobos. Both are situated considerably south of the extreme northern point of the Gulf of California, it being considered inadvisable to attempt to build a terminal farther north on account of the gigantic tides which make the north end of the gulf an unsafe harborage. It is understood that officials of the Calumet & Arizona Mining Co. are interested in the plan.

THE MINING SUMMARY

ARIZONA

Ajo.—Recently a fire occurred in one of the large wells of the New Cornelia Copper Co., which supplies water to the leaching-plant and the town of Ajo. The fire, which was probably caused by defective insulation, broke out near the 700-ft. level, and threatened the loss of the well. In order to avoid a repetition, the company has decided to fireproof the entire well by guniting all the timbered sections.

Kingman.—The production in May of the United Eastern is given as \$175,018, the ore averaging \$22 per ton.—It is reported that the IXL property, one of the old properties of the district, lying about 14 miles north of Kingman, has opened up rich silver ore.—At the Cycle mines the mill is said to be running smoothly and high saving is being made. The ore which is being milled averages about \$12 per ton.

Tucson.—The Arizona-Tucson Copper Co. expects to install additional equipment on its property. The double-compartment shaft has reached a depth of approximately 200 ft. The material in which the shaft is being driven is heavily impregnated with iron and copper, greatly oxidized.

CALIFORNIA

Amador County.—The work of unwatering the Fremont property near Drytown is progressing satisfactorily. Already the Gover shaft has been drained, that shaft being about 1500 ft. deep, and good headway is being made in the Fremont. The latter has a depth of over 3000 ft. and considerable stoping has been done from the various levels. Relay pumps are to be installed on the 1500-ft. level to make short work of lifting the water from the lower levels. Excessive working costs, due to war conditions, caused the Fremont Consolidated Mining Co. to cease operations two years ago. The property comprised four mining claims, covering 4200 ft. on the Mother Lode, and bears a good record as to the size and continuity of its orebodies so far developed. Alex Ross, formerly in charge of the underground operations at the Kennedy mine in Jackson, is superintending the re-opening of the Fremont workings.

Placer County.—The new 10-stamp mill at the Rising Sun mine, a short distance from Colfax, is working steadily on good ore. Indications in the lower levels of the old producer are encouraging. A small vein has been uncovered and this is adding to the mill production.

Sonora.—High-grade gold ore has been encountered in the Jones-Tarantula property at Shawmut, according to advices from the property. The discovery is said to be highly important and opens to development a wide area of new ground. Development of the group has been in progress several years with varying results. Henry T. Gage is understood to be one of the leading owners of the property, which adjoins the noted Shawmut mine.

At the Shawmut property, operated by the Belmont Development Co., of Tonopah, mining is proceeding at full capacity. The mill is running steadily on ore of excellent character and development of new shoots in the lower workings continues to give results. The property is the leader among Tuolumne county producers and one of the premier mines of the entire Mother Lode.

Yuba County.—Development work at the Horse Shoe

mine at Challenge, which is owned by Joe Supple, ship-builder of Portland, Oregon, has shown such favorable indications that a five-stamp mill will be erected. An outcrop of ore over 200 ft. long has been exposed. A five-stamp mill at the Rose mine has been purchased by the management of the Horse Shoe company and is being transported to this property. Will Belk is superintendent.

IDAHO

Bonner County.—The Clarksfork Copper Co. will sink to the water level, 100 to 150 ft., from a point on the vein where it was intersected by the tunnel. The vein has been followed by a drift for 40 ft. Two shifts will be employed.

Coeur d'Alene.—Directors of the Silver-Standard Mining Co. contemplate an early meeting at which they propose to let a contract for additional tunnel-work on their property in McFarren gulch, south of Osborne. They plan to let 50 ft. of work at a time. It will be done in tunnel No. 3, which will give considerable depth.—The Bullien Mining Co., in the St. Joe district, will build a mill of 100 tons daily capacity. The quantity of ore in sight is sufficient to supply a mill of this capacity for several years.—Ore in a body 6 ft. wide has been disclosed by a diamond-drill in the Nipsic property of the Callahan Zinc-Lead Co. It was reached from the 600-ft. level of the Callahan and can be opened by 400 ft. of cross-cutting. The core of the drill suggests the presence of 2½ ft. of lead-silver ore, 2½ ft. of zinc ore, and the remainder a mixture of lead and zinc.

If the ore widens and improves the Ajax Mining Co. will make provision for sorting and washing the ore as it comes from the shaft. A hoist with capacity to sink 300 ft. has been installed. Ore has continued for the entire 35 ft. the shaft has gone, and is from 6 to 12 in. wide, of better grade than previously found. Fourteen men are employed.—The Cedar Creek Mining Co., at Wallace, shipped a carload of ore to the Bunker Hill smelter which netted a return of 68.9% lead and 9 oz. silver per ton.

The Copper King Mining & Smelting Co. has completed a raise of 200 ft. from the tunnel-level. The raise has been in ore practically from the beginning, with only one wall of the vein in sight; it opens only a small section of the orebody. Hand sorted ore, removed in the course of raising, contained 20 to 48% lead and 10 to 20 oz. silver per ton. The raise has passed through three streaks of high-grade ore. The remainder of the filling is low-grade mill-feed.

MISSOURI

Joplin.—One of the largest companies operating in the Tri-State district is said to have taken leases on land near Galena, at one time the busiest mining town in the district. A deep run of ore is known to exist, and the company has obtained almost 1000 acres. A few years ago zinc ore was found at 485 or 490 ft. in the drilling of a deep well for city water. The report is that the orebody is more than 10 ft. thick, the ore assaying 8% or better in zinc with a trace of lead. Numerous other deep holes in the Galena field show the presence of zinc orebodies at depths considerably lower than has ever been mined in that district.

The program of drilling started by the Webb City &

Carterville Development Co. seven or eight months ago in an effort to find lead or zinc on new leases is continuing. Three drills are at work but, while indications are favorable at one or two places, no real orebody has been found.

MONTANA

Great Falls.—The Anaconda Copper Mining Co. is said to be considering doubling the capacity of its rod and wire-plant. Operations have been conducted practically at capacity at this plant from well along in 1919 up to the present time, and orders are now in excess of the ability to care for them with present manufacturing capacity. The plant calls monthly for a maximum of 8,000,000 lb. of copper. The company has given more than a passing thought to the possibility of the manufacture of brass at Great Falls, where the company has an adequate supply of refined copper and zinc at hand for alloying into brass. Anaconda has been successful thus far in disposing of its electrolytic-zinc output, and the activity of the company in developing its silver-zinc properties would suggest a confidence in better prices.

NEVADA

Mina.—Cross-cut 701, on the seventh level of the Simon silver-lead mine is being driven west in search of the segment of the orebody thrown off by the west fault. Raise 705-A is being driven from the seventh level to the sixth level, 150 ft. above.—At the Simon Contact property a silver-lead-zinc orebody has been drifted on along the 350-ft. level for more than 50 ft. Average samples returned 56.4 oz. silver, 23.6% lead, 22.5% zinc, and \$1.60 gold per ton. Indications point to the orebody being the top of a shoot of considerable size.—Contractors engaged in sinking the shaft on the Fagan Consolidated Silver Mines property have completed the first 100 ft. of the work.

OREGON

Gold Hill.—It is reported that the Chisholm group of mercury mines, adjoining the War Eagle property, that has been worked in a crude manner since 1878, will soon change hands and a large Scott furnace will be erected at the works. This mine is equipped with a 12-pipe furnace operating on high-grade ore.—The Force group owned by David Force of Beagle, is likewise equipped with the pipe-type furnace, but recently-developed rich ore warrants the purchase of a large-capacity furnace.

Obituary

Philo Taylor Farnsworth, a widely known mining man of Utah and Nevada, died at his home in Salt Lake City on July 19, following a two-days illness of acute intestinal poisoning. Mr. Farnsworth was born October 15, 1849, at Salt Lake City, of New England parentage. While a young man he saw active service in the Black Hawk war and other Indian wars in the early days. At one time he was mayor of Beaver City, and later represented Beaver county in the Utah territorial legislature. For twenty years Mr. Farnsworth was manager for the Horn Silver Mining Co. near Frisco, Utah. He also served as manager for the Bullion Beck Mining Co. at Eureka, Utah, for about twelve years, and for about the same length of time was manager for the Austin Mining Co. at Austin, Nevada. Besides these properties, he was identified with the Dalton and Lark mines at Bingham and had numerous other mining interests in Utah and Nevada. Mr. Farnsworth was an enthusiastic supporter of education, and donated liberally to the various institutions of learning in the State. Among his donations was the presentation of the Fort Cameron property in Beaver county, which he purchased from the Federal government, to the Mormon Church. This is now the home of Murdock academy. Mr. Farnsworth is survived by a widow and eight children.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. L. Bosqui was in San Francisco last week.

James McKeen, of Cherry Creek, Nevada, is here.

Keith Roberts is at 203 Reaper block, Chicago, Illinois.

Percy Williams, of Silverbell, Arizona, is in San Francisco.

H. Brehm has left Bolivia and is now at Greiz, Germany.

John Kiddie and J. Webster are visiting the Globe-Miami district.

Robert S. Davis is with the Alvarado M. & M. Co., at Páral, Mexico.

M. Albertson has moved from Turon, Kansas, to Shreveport, Louisiana.

Lyman H. Brooks Jr. has gone to Cooke City, Montana, to examine mines.

Frank L. Sizer has returned from professional duties near Phoenix, Arizona.

F. Le Roi Thurmond has gone from Santa Barbara to Chihuahua, Mexico.

H. E. Queen, of Berkeley, is now with the Candelaria Mines Co., at Candelaria, Nevada.

L. R. Wallace, manager for the Andes Copper Co. at Portrerillos, Chile, has been in Utah.

Charles Butters has returned to Oakland from Mexico, and is now proceeding to New York.

A. E. Drucker, of the Wisconsin School of Mines, has been visiting the Tacoma smelter and refinery.

George W. Lloyd and Charles J. Worden, mining engineers, have opened offices at Quincy, California.

Francis Drake has gone from London to Melbourne. He will be in Australia until the end of September.

Roy Hatch has been appointed superintendent of the Arthur plant of the Utah Copper Co. at Garfield.

W. J. Sharwood, metallurgical chemist to the Homestake Mining Co., was in San Francisco during the week.

L. Venn Brown has resumed control as general manager for the King Island Scheelite Co., at Grassy, Melbourne.

M. W. Hayward has returned to Denver from South America, whither he went to examine mines for the American Metal Co., Ltd.

Edwin E. Chase and his son, R. L. Chase, of Denver, have gone to the San Juan district of Colorado to examine mines at Ouray, Lake City, and Rico.

James T. Norton, ore-dressing engineer, has been transferred from the station of the U. S. Bureau of Mines at Moscow, Idaho, to the station at Salt Lake City.

N. M. Muir has opened an office for general mining and petroleum work at 425 Flynn Ames building, Muskogee, Oklahoma. He retains his office in the Mills building, San Francisco.

T. A. Janney, superintendent of the Arthur plant of the Utah Copper Co., has been promoted to the position of chief metallurgical engineer in charge of all the company's plants.

H. C. Bellinger has been appointed vice-president of the Chile Copper Co. and will make his headquarters at New York. Burr Wheeler succeeds Mr. Bellinger as general manager at Chuquicamata.

At the recent commencement of the University of Pittsburgh, the honorary degree of Doctor of Science was conferred upon Professor H. H. Stock, head of the Department of Mining Engineering, University of Illinois.

Charles G. Yale remains in charge of the U. S. Geological Survey's office in San Francisco. An impression to the contrary has been given by a badly worded paragraph in the 'Engineering and Mining Journal'. J. M. Hill comes as a welcome associate, not as a successor, to Mr. Yale.

THE METAL MARKET

METAL PRICES

San Francisco, July 27

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.00

Quicksilver, per flask of 75 lb.....	\$88
Spelter, cents per pound.....	9.25
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

July 26.—Copper is quiet and steady. Lead is strong and higher. Zinc is dull but easy.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

THE RAILROADS

Railroad operating results reported by the Commerce Commission for the first five months of this year indicate the carriers would have earned in the period, with the 19¼% increased revenue asked in the present rate case, slightly less than the pro rata share of the \$1,236,000,000 necessary to show 6% return on property investment. This in spite of the fact that several adverse factors contributed to make the results in that period unsatisfactory.

Estimates made public by the Commerce Commission show that the railroads in the first five months of this year had a total operating revenue of \$1,781,063,569 and expenses of \$1,631,655,489. Net operating income was \$149,233,347. If this revenue had been 19¼% greater, as is designed in the revision of rates suggested to the Commission, net operating income would have been increased by about \$357,000,000, bringing it to \$405,000,000 for the five months.

In the first five months of the year railroads normally, as shown by the test-period, earn 35% of the total year's operating income. On this basis a net operating income in the first five months of \$405,000,000 would indicate net operating income for the year of \$1,157,000,000, only \$79,000,000 short of the amount necessary to show 6% return for the year. The property-investment accounts of the railroads aggregated \$20,618,000,000 on October 31, 1919. To show a return of 6% on this total, it would be necessary for the railroads to have a net operating income of \$1,236,000,000.

In view of difficulties under which the railroads were operating during the early part of this year this showing should be considered excellent. For the first two months they were under government operation. When returned to their owners, rolling stock and road-beds were generally below standard, so that it is understood maintenance expenses for succeeding months were unusually high. Traffic was interrupted by the steel strike, and later by strikes of yardmen, shommen, and other railroad employees. In addition it has recently been impossible to operate railroads in many parts of the country at maximum efficiency, because freight offered for transportation has been in excess of the capacity of the roads to handle, necessitating priority orders and special handling.

The railroads, it is understood, have no intention of restoring the two-weeks credit extended to many patrons prior to Federal control. In accordance with regulations prescribed recently by the Commerce Commission, railroads authorized their agents beginning July 1, to allow patrons on their credit lists 48 hours credit that is, until morning of the second business day following rendering of bills, to settle charges, this privilege being extended for 48 hours additional credit only on the patron filing a bond satisfactory to the treasurer of the railroad.

Before the railroads were taken over by the Government it had been the custom to allow certain patrons, who had filed applications with the railroads and established their responsibility, to delay payment of freight bills, two weeks being the generally recognized limit. The Railroad Administration discontinued this practice, and the 'cash credit list' was established. A recent ruling of the Commission restores the practice of extending credit, limiting the time, however, to two days in ordinary cases and four days for those who file bonds to ensure payment.

Marks, cents			2.55

Eastern Metal Market

New York, July 21.

All the markets are quiet but strong with prices higher in one or two.

Buying of copper is satisfactory and prices are steady and firm.

The tin market is quiet and transactions are confined to dealers.

The lead market is very strong and prices are advancing.

There is not much activity in zinc but values are firm to higher.

Antimony is unchanged.

IRON AND STEEL

Appraisal of the effect of the 21% advance in railroad wages is not easy in the absence of clear indications of the attitude of the unions. In the steel-trade the more general opinion is that a widespread strike is not likely. The increasing signs of reaction in various industries are cited as having an important bearing.

Steel manufacturers look for some relief from the difficult conditions of many weeks, with the return to work of experienced railroad workers, but it is recognized that improvement will be slow and it is admitted that the accumulations of product are more than have been commonly known.

While the Steel Corporation has only 60% of its tin-plate capacity in operation, independent makers are doing better, the average for the entire industry being put at 75%.

Structural work is falling off sharply. June reports show 90,400 tons booked by fabricators or 50% of the capacity of the country.

COPPER

There is little change in general conditions. Buying is moderate and fairly satisfactory from both domestic and foreign sources, the purchases extending into the fourth quarter in some cases. The large producers are maintaining their prices firmly at 19c., New York, for both Lake and electrolytic copper, with some sales for fourth-quarter delivery made at 19.25c. In the outside market, so-called, small producers and dealers are quoting both grades of copper at 18.75c., New York. While there are no indications of a heavy buying movement, the situation is fairly satisfactory and the volume of business is good.

TIN

This market continues quiet with the only business reported confined to the buying back by London sellers of contracts. This has been the feature and is an event that is infrequent. It takes place usually when the market here is below the cost of tin importations. Because of this situation there have been few London sellers and the market has been consequently quiet with demand for spot and other positions small. Consumers continue to remain uninterested. Sales on the New York Metal Exchange have been light also. Spot Straits yesterday was quoted in New York at \$49.50, with \$288 per ton the value in London. Arrivals thus for this month have been 2365 tons, of which 720 tons is credited to Pacific ports. The quantity afloat is 5700 tons.

LEAD

Pronounced strength characterizes the market. This is due to an intensification of the underlying conditions that have prevailed for two or three weeks. There continues to be a deficiency in supply of the metal and consumption is exceedingly heavy. Production does not increase enough to overtake demand and transportation troubles have been and are still a factor. The quotations of the American

Smelting & Refining Co. of 7.75c., St. Louis, or 8c., New York, are nominal, as that company is not selling. We quote the outside market as 8.50c., St. Louis, or 8.75c., New York, with prompt metal actually sold as high as 9.12½c., New York, and still offered at 9.25c. For prompt shipment from the West the metal has sold at an equivalent of 8.90c. New York. Import lead has been offered at 8.62½c., duty paid, which would indicate that such metal is likely to appear despite the belief that the price of the lead-interest is kept low to prevent this.

ZINC

There has been little change in conditions. Prices remain steady, to strong, with the tendency upward. There has been a depletion of stocks in the hands of producers and production has been slowed-down recently, which makes for a strong technical position. Most large sellers are disinclined to sell beyond August and are not anxious to buy at present levels, which are not much, if any, in excess of cost. Demand is fair from domestic consumers. We quote the market for prime Western at 7.95c., St. Louis, or 8.30c., New York, for early or July-August delivery, with some sales made into September at this level. There has been a resumption of mining in the West, several mines having been closed about three weeks ago.

ANTIMONY

Conditions are unchanged and wholesale lots for early delivery are quoted at 7.50c., New York, duty paid.

ALUMINUM

The leading interest is quoting 33c., New York, for wholesale lots of virgin metal for early delivery. The same product can be obtained from other sellers at 31.50c., New York.

ORES

Tungsten: There is no activity and the market remains featureless. Quotations are nominally unchanged at \$6 per unit in regular 60% concentrate.

Ferro-tungsten is in moderate demand at 80c. to \$1.05 per pound of contained tungsten.

Molybdenum: There is no life to this market, with quotations nominal at 65 to 75c. per pound in regular concentrate.

Manganese: Caucasian ore has been offered at 80c. per unit, seaboard, for shipment in September, October, and November. Indian ore has also been offered at the same figure. It is believed that no more than 70 to 75c. per unit, seaboard, would now be paid by users.

Manganese-Iron Alloys: The market is quiet with demand confined largely to small lots for prompt and early delivery. There is one inquiry for 600 tons for delivery in August, September, and October at 200 tons per month. Quotations are firm at \$225 for spot and \$200 for last-half delivery. The spiegeleisen market is quiet but firm at \$75, furnace, with moderate sales for early delivery.

The Antwerp diamond-cutting industry is passing through a depression unequalled since the American financial crisis of 1907. The industry normally employs about 13,000 men. Some 5500 are now without employment, and the industry is working at only about 50% of normal capacity. The chief cause of this depression is the almost complete suspension of orders from the United States. American buyers are usually relied on to take more than half of the Belgian output of cut diamonds. Extraordinary demand for diamonds in the United States following the Armistice has, however, been followed by a reaction.

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 3514 Woolworth Bldg.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

Enviably Records for Large Capacity and High Extraction

Over twenty-two thousand Wilfley Tables are now in use. Wilfley users are found in practically every mining district in the world. Some of these tables were installed twenty years ago. All are making enviable records for large capacity with high extraction.

At the Nevada Consolidated Copper Company, McGill, Nevada, you will find more than 500 Wilfley Tables. They have been in active service over ten years, yet still giving splendid service.

The Consolidated Copper Mines Co., Kimberly, Nevada, is a recent installation where Wilfley Tables are making a highly satisfactory showing.

There is a type of Wilfley for every possible requirement. The latest Model, No. 11-D, embodies all improvements. This table is especially suitable for the foreign or isolated

operator in that this design eliminates about 40% of the shipping weight of the same sized steel frame table.

STATISTICS of gold production in Rhodesia show an eccentricity for the month of May, the value of the output being nearly double that for April, although the quantity of gold produced during the two months was nearly the same. The anomaly is explained by the fact that to the value of the actual May output there was added nearly £200,000—to be exact, \$197,043—on account of the gold premium during the period from October 1919 to January 1920. Thus in the three months the premium was about equal to the normal value of a month's output.

ON his return from Pachuca to London, Mr. Alfred James was interviewed by the 'Financial Times'. We note that he reports favorably upon conditions in Mexico. The people are tired of revolutions, he says, and ask only to be left quietly at work. Obregon is described as "firm and able". Mr. James makes a sly dig at us when he says: "Whatever the future of oil in Mexico may be—and the demand is very great while the territory so far proved productive is extremely limited—there can be no doubt that the enterprise of the British mining and other companies who have devoted themselves to the exploitation of Asia, South America, and other oil districts will, before long, be as highly appreciated by the investor generally as it appears now to be by our American cousins." Boy, page Senator Phelan!

AN excellent example of extending the life of a mining enterprise by the acquisition of new property elsewhere is afforded by the Oroville Dredging Company. This started by acquiring and exploiting gold-dredging property at Oroville, California, in 1905. The first company was registered in Maine and was succeeded four years later by an English company, which purchased large dredging areas at Pato and Nechi, in Colombia, two subsidiary companies being organized in 1909 and 1914 respectively. The original American company, controlled in London, is now being liquidated, as the ground at Oroville has been worked out; it paid 37½% on its capital of \$3,500,000 up to 1909, and since then its successor has paid 47½% on an equal amount of capital. Oroville Dredging started badly; the ground was purchased on an appraisal made largely by the vendor's engineers and proved to be considerably less profitable than was anticipated; in consequence, the company was over-capitalized. These early blunders have been re-

trieved, in large part, by the later extension of the company's activities to South America. Last year the Pato earned \$29,724 on a capital of £100,000, of which the Oroville company holds £70,000; likewise the Nechi earned £61,995 on a capital of £140,000, half of which is held by Oroville shareholders. The success of this enterprise is shared by Mr. W. A. Prichard, the mining engineer responsible, and Mr. F. W. Baker, the chairman of the three companies.

SECRETARY DANIELS and Secretary Paine obtained valuable information from their inspection of the Chicaloon coal mine in the Matanuska field. So says an official bulletin issued by the Navy Department. What information the publisher of a country newspaper and a very able lawyer could gather between them concerning an extremely difficult phase of coal mining, we leave the reader to conjecture. We are in no doubt as to the value of it. It is not recorded whether the Honorable Josephus was accompanied by a mining engineer, but we note that Mr. Sumner S. Smith has been given charge of coal mining for the Navy under the Alaskan Engineering Commission. Strange as it may seem, we have a respect for the opinion of a mere engineer like Mr. Smith such as we confess to lacking entirely in respect of the Secretary of the Navy—that is, in regard to coal mining, of course.

IN this issue we publish the remainder of the article by Mr. Charles A. Mitke on mine-fires in the South-West. Mr. Mitke has devoted most of his time during recent years to the study of those phases of metal mining that have to do with systematized operations as distinguished from the exploration for, and development of, ore. He is thoroughly informed on nearly every mine-fire in Arizona, not only in regard to its origin and cause but as to the measures taken to isolate or extinguish it. The causes of 35 active fires in the copper mines of the South-West are given by Mr. Mitke as follows: careless use of candles, 3; defective electric wiring, 5; friction from movement of sulphide orebodies, 11; incendiarism, 15; and unknown, 1. The efforts of mining companies today are directed primarily toward preventing, rather than fighting, fires. Modern equipment and organized plans for inspection and immediate action in emergency make an unexpected fire of any size almost impossible. Even should a small blaze start, it could gain no headway. In June 1917,

electricians were lowering a lead-armored electric cable in the Granite Mountain shaft of the North Butte Mining Company. The tackle broke, and the cable fell in such a way as to tear off much of the armor and expose the highly inflammable insulation beneath. A mine foreman, engaged in recovering the cable, accidentally lighted this insulation with his carbide lamp and the shaft-timbers burst into flames. The workings were filled with smoke and 171 miners were suffocated. This catastrophe served as a lesson to operators throughout the West and encouraged the adoption of sprinkler systems, concreted shafts, 'gunited' stations, fire-doors, bulkheads, and similar precautions. A few weeks ago a timbered well that supplies water to the New Cornelia company's leaching-plant at Ajo was threatened by a fire near the 700-ft. level. We are informed that the timbers will be coated with 'gunite' (sand and cement applied with a pneumatic gun) to avoid a second fire, which might be more disastrous. One of the most important requirements is an adequate system of mechanical ventilation. Not only does positive uniform ventilation minimize the danger of loss of life, and reduce the cost of fighting fires, but it may in a large measure prevent fires in sulphide ore-bodies by keeping the temperature below that necessary to start combustion. Mr. Mitke's articles may well be read by every mine manager and superintendent, for fire is no more a respecter of mines than of buildings.

WE take pleasure in publishing another letter from Mr. Charles Butters, in advocacy of the greater use of silver coin. Whereas we think there is little chance of supplanting the use of checks and other forms of paper money in the United States by the circulation of silver dollars in ordinary business transactions, we do appreciate the conditions that may render such a proposal feasible in Mexico. There, at the present time, the currency consists mainly of American silver coin and *bilémbiques*, or promissory notes, besides the various kinds of fiat money printed by successive presidents and *de facto* governments, alive and dead. The Mexican naturally looks askance at all forms of paper currency, the value of which is doubtful and subject to discount. In his small dealings he needs silver, of which in coined form there is not enough to go around. What more reasonable than to coin the silver metal produced by the mines of Mexico and put the product into immediate circulation? In this country we would not care to carry or hold more than five silver dollars at a time; they are clumsy; we prefer to convert them into bank-notes, the value of which is incontrovertible—at least for ordinary purposes. The Mexican peon is not unwilling to load himself with heavy coins, preferring to put them under the hearth or in some other safe hole rather than exchange them for doubtful paper. If the silver of the mines—for instance those owned by Americans, like Mr. Butters—is coined by the Mexican government, then the mine-owners, instead of exporting bullion at considerable expense and subject to sundry duties at both ends, could use their Mexican dollars to buy Mexican products

for export to the United States. For example, they might buy carloads of the highly nutritious chick-pea, *garbanzo*, which General Obregon is exploiting so successfully in Sonora. They might buy other products, such as *henequen* and *gayule*, hides and wool, from other deserving Mexican citizens, many of whom, most properly, on account of their unusual intelligence, are now officers of the Government. It seems to us that the Butters idea is commendable for many reasons, the chief of which we mention last, namely, it would take Mexican silver off the American market by putting it to a beneficent domestic use.

GEORGE WHITE, the new chairman of the Democratic National Committee, is interesting to miners because soon after graduating from Princeton he made the adventurous journey to the Klondike during the rush of 1898 and remained there three years. He was one of the lucky men who came away with a fortune—nothing big, but enough to start him in successful oil speculation. It is said, in the 'New York Times', that he gave a talk on his experience as a gold-miner before a church club at Washington and in the course of his description he told his hearers about digging 72 ft. through frozen ground to reach the gold, which was separated from the gravel by washing with water. Whereupon Mr. James M. Cox, then a member of Congress from Ohio, twitted him for asking intelligent people "to believe that where the ground is frozen 72 ft., running water is found". Many of our readers know how to explain the apparent discrepancy. The freezing of the ground is due, not to the cold of the preceding winter, but to the cumulative effect of a long period of excessive cold, namely, the Glacial period. The ground is frozen three hundred feet deep, or as deeply as the water percolates from the surface. The gold-bearing gravel used to be thawed by wood-fires, later by steam, and now by unheated water, as described in our issue of March 13, 1920. After the gravel has been brought to surface, mainly during the long winter, it is washed in summer, when for three months, or slightly more, the air is as warm in the Klondike as in Idaho or Oregon. Running water is plentiful, even if it runs over frozen ground, for the bedrock is in the grip of a primeval frost and only the surface surrenders to the summer sun.

Geologic Fallacies

Speaking of real mines, we have been favored with a report on one owned by the Sulphide Mining Company, near Chelan, in Washington. The description has been written by the secretary and treasurer of the company, who judging by his name and by his literary style is of Scandinavian origin. His conclusion is that "from all indications here in time to come will be one of the greatest mines of the United States". That time may come, if the physical forces at work in the crust of the earth succeed in concentrating valuable metals with sufficient intensity at this particular spot, but it is more than probable that we shall be "ancients of the earth and in the

morning of the times" when that happy event supervenes; our Recent period will seem Algonkian to the descendants of the deluded mortals who will have bought Sulphide Company stock. The little prospectus is a good example of meretricious statement. For example, the ore assays 0.3% in copper, representing \$1.20 per ton; 9% in lead, equal to \$9 per ton; 16.7 oz. silver, worth \$16.70; and "15 hundredths per cent" in gold, equivalent to \$3.10, making a total of \$30 per ton. Of course, he means 0.15 of an ounce of gold, but that is a negligible error compared to the adding of the assay-values of a number of metals, the presence of which may prove metallurgically conflicting. He adds: "It will be noticed that I did not have this sample [he estimates the value of the vein from the assaying of one sample] assayed for zinc, and there is no doubt that there was considerable zinc in the same." The suggestion that the money to be made from the exploitation of an ore is measurable by adding the nominal value of each of the metals it may contain is a fallacy that has been told "to the marines" and to other supposedly gullible people from time immemorial. He obtains a poorer assay from a sample taken 400 feet higher on the surface of the mountain and thereupon concludes: "This, in my opinion, demonstrates that the deeper one comes on the ledge the richer the ore will be." Another worm-eaten fallacy; as if the finding of \$5 ore on the top of a mountain and of \$15 ore at the surface a thousand feet lower proved that the ore became trebled in richness if followed to a depth of 1000 feet below the surface. All the experience of mining, not to mention the knowledge of the ways in which outcrops are enriched in places, contradicts the inference of the simpleton. The conditions affecting surficial enrichment are measurable usually not from a former imaginary horizontal surface but from the surface of today. Another sapient observation made by our Scandinavian pseudo-geologist is as follows: "There have been tremendous forces at work which could not develop from only a few hundred feet below the surface, but have issued out of depths thousands of feet below the surface, and therefore these ledges will not work out, but go to unknown depths; and no one needs to be afraid that the ledge or ledges will be lost and not found in driving a tunnel at a great depth." Tell that to the suckers; it has been told them so often, they may believe it! As if the continuity of a fracture in granite ensured the persistence of the ore with which it is filled at the surface or near it; or as if the deep-seated origin of the geologic forces that formed the fracture made certain that it would reach to great depth. A river does not widen toward its source nor does a crack enlarge in approaching the place of its origin. If these foolish notions, long ago exploded, concerning veins were true, we would save time and energy by sinking a mile forthwith, leaving the shallow zone to the timid technicians who still think it best to be guided by observed facts and logical induction therefrom. But the best—or the worst, if you will—is yet to come. On the top of the "ledge", the Scandinavian and another of the same ilk, judging by his name, found "all slag, showing the tremendous heat and the forces that have been working".

The vein was capped, so they say, with geologic slag, which apparently had been cooled by the snows of today, for mention is made of the fact that "the lower expanse is all covered with snow". Another inference is made: "No minerals have been discovered in this ledge, and I think for the reason that a certain depth has to be reached before minerals appear." What then, have we here an undifferentiated magma! But why should it cap a vein containing no minerals; is this according to Hoyle or Kemp, or even in accordance with U. S. mining regulations? A vein without minerals is as rare, if not as self-contradictory, as a tree without wood or a politician without talk. So, it appears, if a vein contain several kinds of metallic minerals, they prove its potentiality of wealth in depth, at Chelan, Washington, no matter how much they may interfere with the extraction of the more valuable of the metals. "But suppose", says our pseudo-geologist from the land of the vikings, "that minerals are found in this ledge on a depth from 50 to 100 feet and then down, what an unlimited quantity of ore is here in store." Supposing, supposing—well if a pair of barnyard fowls can produce eight chickens, and the eight chickens proceed to business like their parents, then 64 more chickens will appear, and if the 64 get busy, why, there will be a whole lot of chickens, and so *ad infinitum*. After all, 'minerals' do not make a mine and even a 'ledge' is not a treasury. As Bossuet said, the greatest aberration of the mind consists in believing a thing because it is desirable.

The Salting of Mines

In our issue of July 24 we gave our readers a humorous article on a phase of fraud in mining transactions written by one who is a kindly spectator of what the newspaper reporter calls the mining 'game'. Fiction, even when funny, is not stranger than fact; indeed to be funny it must be linked with fact sufficiently to include an element of probability. The doings described by Mr. Hutchinson have their parallel in real life. We are reminded of the description of an elaborate piece of salting recounted by Mr. Walter McDermott in a paper read before the Institution of Mining and Metallurgy in London in 1894. Mr. McDermott is an engineer of such successful experience and proved sagacity that he could confess himself to have been beaten once by a curious combination of circumstances favorable to a particularly systematic and ingenious scheme of salting. An English engineer brought a series of average samples and half a ton of average ore from a silver mine in the West to Mr. McDermott, who was then living in New York. The samples assayed well and the ore proved docile to ordinary treatment, so the engineer's report was a glowing one. However, for financial reasons, the deal in London fell through. A year later the owner of the mine came direct to Mr. McDermott, who took an option for an English company subject to an examination. Before doing so Mr. McDermott obtained a report from an engineer in the West, confirming the owner's statements. In addition, he received a statement from two other

Western engineers stating that the mine would prove valuable if the ore were milled on the ground instead of being selected for shipment to the smelters. Thereupon he himself went to the mine and sampled it carefully, taking more than half a ton of samples, in sacks that were sealed in the mine by wire through and around the necks, and held by a special lead seal. It was a question whether the full width, six feet, of the lode was rich enough to be milled successfully on a large scale, or whether only a small part of it could be treated profitably on a small scale. In addition to his 25 average samples, he took seven full-sack samples from different parts of the mine, each of these consisting of large lumps of the poorer ore without any fine stuff, the idea being that they would be immune from salting because they could be cleaned easily, so that any 'salt', in a fine or a liquid state, could be removed before assaying. In an evil moment he had to change his program, for his clients pressed him for a preliminary report, whereupon he decided to crush five of his seven bulk-samples at a local sampling-works. He took the usual precaution of cleaning the crusher and rolls himself, dusting the lumps beforehand, as well as quartering the pulp himself and taking samples in duplicate. One set he handed to a local assayer, whom he knew to be interested and whom he could not trust unchecked. The second set of samples he kept in a valise in his own bedroom, but, as was ascertained later, the assayer was in collusion with the vendors, the entire mining camp was involved in a conspiracy six years old, and somebody managed to enter his room and doctor his check-samples. He still had two, which were sent to New York, but, as bad luck would have it, he was delayed by other business in returning thither and the samples arriving before he did they were crushed and assayed by his assistant in New York without taking the precaution to clean the lumps. So this check proved unavailing. Into each sack was introduced a dose of finely divided silver such as is obtained from leaching plants using copper-plate precipitation. As a matter of fact, the lump samples contained naturally only two to three ounces of silver per ton, but when 'doctored' or 'fixed' they assayed 20 to 30 ounces. The smaller samples of crushed ore were 'got at' afterward. In each one Mr. McDermott found, by panning and the use of a microscope, particles of fine metallic silver such as did not exist in the mineral itself. This sinister fact he discovered in the course of milling tests, and it raised suspicion sufficient to cause him to endeavor to re-sample the mine, but again the force of circumstances beyond his control and the skillful actions of the gang at the mine sufficed to defeat his purpose. To this unfortunate result his own clients contributed by their anxiety to consummate the deal, refusing to consider the chance of error in view of the previous good reports and the insistence of the vendors upon a prompt decision. Shortly after the purchase had been made he re-sampled the mine, the first assays disclosed the fraud, and he informed his clients by cablegram that they had been deceived. He proceeded to bring the matter home to the perpetrators. After four years of hard work he was able to get a sweeping judgment against the vendors. It was

disclosed that the English engineer, who made the first report, had not sealed his sacks; he had tied them with a string and had crushed his samples at the local mill before shipment to New York. The gang had been able to empty his sacks and fill them with selected ore. Unfortunately these samples, after being assayed in New York, were thrown away in due course, but one sealed bottle containing a mixed average of the English engineer's samples was found and upon examination it proved to be free from any metallic silver. This served as evidence in the trial of the case. An American engineer, who took small samples and sealed them with the end of his penknife, took the samples himself to the express company's office at the nearest railway station, but the agent was persuaded to let the vendors have a look at the samples. They opened the sacks, changed the contents, and re-sealed the packages, using a penknife as the expert had done. The more experienced Western engineer had taken his samples carefully, quartered them in the mine himself, and sealed them in sacks, using a seal bearing his own initial. He also delivered them to the express company's agent in person and therefore felt safe. At midnight the agent and two of the vendor's gang set to work. To avoid breaking the seals, they opened the sacks at the bottom, at the seam, and re-sewed them neatly after substituting a grade of ore more satisfactory for expediting a sale. As Mr. McDermott remarks: "A sack that has the sewing of the join inside, and is sealed at the mouth, cannot be opened at the bottom and re-sewed with absolute impunity; but the opening need not be large, and with neat work, and the big chances of the expert having absolute confidence in the express company or post-office after he has personally delivered his samples, the business can be done." It was, in this case. Moreover the vendor's representative had the foresight to take a copy of the seal on the sacks and had one made for himself. The story is worth re-telling, if only to show how even many precautions will sometimes fail to prevent or to detect 'salting' until it is too late. The use of a magnifying glass to examine the ore is an excellent precaution. Mr. McDermott relates how, when examining an alleged silver prospect in South Dakota, he detected particles of silver to which traces of native copper were attached. On questioning his guide, he found that he had worked in the Lake Superior mines. That sufficed, for the association of native silver and native copper is almost unknown save on the Keweenaw peninsula. The only absolute protection against salting is to be alone at all stages of the work or else to be accompanied by one's own assistants. When the engineer has to go in a hurry to examine a mine offered for sale on a short option, he may have to accept the aid of people in the mine. Then he is in danger. Clients are often to blame for their insistence upon a hasty decision and for their refusal to allow the engineer to adopt the necessary precautions, chiefly plenty of time and reliable assistance. Two sayings should be written, like an electric safety-first warning, on every engineer's notebook and operator's check-book: '*Caveat Emptor*' and 'It is better to be sure than sorry'.

DISCUSSION

Concerning Silver

The Editor:

Sir—Thank you for your kind notice of my letter, in your issue of July 3, concerning silver. Criticism of any kind is always helpful and enlightening if one only listens carefully enough to the other man's view.

I note your remark that for the silver miner to pay his obligations in his product or silver money "is a pious idea, but we anticipate that those receiving silver dollars would deposit them in the bank, preferring to use checks or Federal Reserve bank-notes". I want to thank you very much indeed for these few lines, because they show me, first, that I had failed to make my argument clear for the silver miner, and, second, that even if the receiver of the silver did not use it but once and then deposited it as mentioned, our object would still have been attained, in part at least.

The silver miner is concerned in the primary marketing of his silver. If the silver is marketed in bars, it can be sold and re-sold, and is a constant menace to the market until it reaches some final manufactured form—the more expensive the form of manufacture the better. Once manufactured into silver salts, jewelry, or plate, it is well off the market, at least for a time. In bangles or anklets on an East Indian woman, where a lot of it goes, it is fairly sure that, for the present at least, it won't bother. With these markets supplied, if the miner goes to the Mint and sells there for the market-price, and receives silver coin in payment, he has put his product into a manufactured form and it takes a price of \$1.29 per ounce for dollars and \$1.38 for subsidiary coin before that silver can come back on his market for re-sale. In that way the miner has accomplished his object of enlarging his market when the price is down, and has reduced the supply to other users.

What brings down the price is trying to sell where there is no demand. When the silver miner sees a falling demand, he should immediately sell his product to the Mint at any market-price and get his output put into coin. When there, it is safely locked up to at least coinage-value. When he pays this out and it goes into circulation the miner has accomplished his object. What is done with it afterward does not interest him so much. If it is carried around and used and gradually wasted by attrition, so much less silver. If it is put in a bank and the banker issues a paper note against it, still the silver producer is satisfied. If the banker can issue two or more notes against it, the banker is satisfied and the miner did him a kindly turn by giving him a basis for

the multiplication of credit, and for the man who wants to borrow there is money and credit where it did not exist before. So it seems to me that the miner, when he coins his silver for his own protection, is in the position of the man who made two blades of grass grow where only one grew before, and I believe such a man is highly respected and looked up to as a public benefactor. If our paternal and non-profit-making Mint buys the silver for, say, 90c. per ounce and coins it into silver at anywhere between \$1.29 and \$1.38, the silver miner, in addition to all the other benefits he has bestowed, has incidentally given the public about 35 to 40c. per ounce on his output, which is at least twice as much profit as he himself has received. The public gets this because the Government has a monopoly on coinage; which all goes to show what happens when the silver miner goes to the Mint with his silver, or what ought to happen.

Now I will tell you just what happens right now, because it happened to me. You go to the Mint with your fine bars and you ask them to coin them at the market price. The reply is, "Yes, but we pay you in gold. We are not letting any silver out at present. We want the silver to get back our reserve." It is a curious attitude. In other words, our policy at the present time is to give gold for silver. The reason may interest the silver miner. The Treasury may think that silver is cheaper now than it will be in the future, otherwise they ought to be willing to pay out silver.

It is to the interest of the silver miner that every means should be taken to lengthen the time of filling the Government reserve, and that can only be done by reducing the amount of silver going into the reserve and increasing the amount going into circulation.

If any reader can tell me on what grounds the Mint can insist on paying for silver deposits in gold, when the depositor of bullion asks for silver, I shall be very glad to learn.

CHAS. BUTTERS.

Oakland, California, July 20.

The Bunker Hill Enterprise

The Editor:

Sir—The statistical summary of the operations of the Bunker Hill & Sullivan Mining & Concentrating Co., given in your issue of May 15, is interesting and valuable; it indicates the great increase in costs that obtain in mining and concentrating ore as compared with a few years ago. This subject is of much interest to me owing to having had occasion recently to review the costs of a

large number of mines situated in Mexico, in which the operating costs have increased from 40 to 100% over those obtaining in 1912.

In making some notes on the table prepared for you of the Bunker Hill costs, I tabulated them for the years since the production passed 300,000 tons per annum, the figures being approximately as follows:

	1904-1911	1911-1915	1916-1917	1918-1919	1919
Stoping	\$1.45	\$1.68	\$2.07	\$2.45	\$2.58
Tramming	0.07	0.06	0.06	0.08	0.08
Concentrating	0.31	0.40	0.58	0.74	0.81
Shipping	0.05	0.02	0.03	0.05	0.06
Superintendence	0.08	0.16	0.16	0.48	0.57
Legal	0.01	0.09	0.06	0.11	0.02
Contingent	0.05	0.06	0.06	0.07	0.13
Total	2.00	2.50	3.00	4.00	4.25
Increase, per cent.		25	50	100	112

There was a steady increase in the cost of stoping, the cost for 1919 being approximately 80% greater than those for the period 1904-1911. Wages and supplies enter very largely into this. I suspect that the price of power had not been increased to any great extent during this period, and hence stoping costs do not reflect the increase that would have applied had the property been using other than hydro-electric power, and therefore the peak for high price for stoping may not have yet been reached. The cost of tramming has suffered almost no change, which might be explained by the same reason as that mentioned for stoping. Concentration shows a maximum increase of 160%, which may have resulted from some extraordinary expenditures in 1919. The most marked increase is in superintendence, amounting to 600%, which would appear to cast a reflection on the good intentions of the present-day workman. In general, the total cost appears to have increased by more than 100% over that for 1904-1911.

Costs in Mexico have increased from 40 to 100% over those of 1912, as noted above. Supplies that are imported from the United States will average probably somewhere between 100 and 150% over those of 1912. Coal and especially fuel-oil obtained in Mexico have not greatly increased, therefore the item of power has not increased in the same proportion as other items. Wages have probably increased 40 to 60% when considering the tendencies produced by several years of revolution.

S. F. SHAW.

Charcas, San Louis Potosi, July 15.

Some Observations on Smelting

The Editor:

Sir—In your issue of July 10, I credited J. H. Klepinger and Peter Thill (or J. H. Klepinger and Archie Wheeler) as being patentees of the process of blowing concentrate and pulverized fuel separately into a reverberatory, whereas I should have credited it to J. H. Klepinger, Milo W. Krejci, and Charles R. Kuzell.

Garfield, Utah, July 16.

C. W. TANDY

[U. S. Pat. 1,160,621 was issued on Nov. 16, 1915, to J. H. Klepinger, M. W. Krejci, and C. R. Kuzell for a

process of introducing oxides of zinc, copper, lead, or other oxide ore, flux, and fuel into a reduction chamber while in the form of dust, so as to fuse, reduce, and separate the metals from the slag.

U. S. Pat. 1,164,653 was issued on Dec. 31, 1915, to the same men, for spraying copper-sulphide ore containing iron into a chamber with flux and powdered fuel, the mixture to be ignited, and air supplied after ignition sufficient to oxidize sulphur and iron, slag the iron, and produce copper sulphide; raw material being added to the fused product to counteract any other oxidation.—EDITOR.]

Ventilation of Mines

Each mine should have its ventilating equipment and system installed by someone thoroughly familiar with the subject. The main fan should be in fireproof housing, equipped for quick reversal of air currents in event of necessity. Air currents should be split underground by a system of doors, overcasts, regulators, etc., in such way that air is quickly removed from the mine after passing through one or two levels, and in the event of a fire in one part, that the fume may be removed without contaminating any other part of the mine. The chief object in ventilating a mine is, however, to bring the moving air to the working face, the most difficult places to ventilate being blind ends. For such places the best results are obtained with small auxiliary fans directly connected to electric motors (1½ to 10 hp.) and forcing 1000 to 5000 cu. ft. per minute at a velocity of 1000 lineal feet per minute to the working place or face. Blower-fans are preferable to the suction type, as they provide rapid movement in addition to removing impure air. Either canvas or iron pipes can be used with blower-fans. Canvas pipes are more convenient and flexible, but iron pipe lasts longer. The last 50 ft. at least should be of canvas for bringing air directly to the face, and for quick removal before blasting and quick replacement after the blast. The most essential feature of metal-mine ventilation is probably that of competent supervision of equipment and practice. Good results cannot be attained if the ventilating system is left without attention, as is the case in many metal mines, nor if left to a mine foreman, who frequently knows little about ventilation. Progressive companies are realizing the value of efficient ventilation at working faces, and in general find the best results are had when ventilation is placed in the hands of one man who devotes all or most of his time to this work. Where this is done the returns in improved safety and health of employees, and in financial return to the company, far outweigh any costs entailed.—U. S. Bureau of Mines.

OWING to the present high price of platinum, there has been a recent great demand for substitutes for it. At one time platinum was used in making incandescent lamps, but in this use it is now almost entirely replaced by tungsten.

A History of Mine-Fires in the South-West—Part II

By CHARLES A. MITKE

From August 1917 until November 1919, the Coronado mine of the Arizona Copper Company suffered from a series of fires, which, unfortunately necessitated numerous shut-downs. All these fires occurred in active top-slice stopes, in which the percentage of the sulphur in the ore was less than 3%.

The Coronado mine extends along a continuous east-west vein, over two miles long. The main haulage-way is on the adit-level, which is the 1100-ft. level in the Coronado mine. The remaining levels are the 500, 600, 700, and 900, which are all in the vein and parallel. The Matilda shaft, extending from the 1100-ft. level to surface (on top of Coronado mountain) is situated one mile

such large volume that it filled both the 655-ft. and 700-ft. levels as far east as the Matilda shaft. This was due partly to the fact that the mine was ventilated entirely by natural draft, and during the summer the air-shaft, though caved by earlier top-slice workings, was a slight upcast during part of the day and a strong downcast at other times.

The part of the mine on fire was worked principally by top-slicing, and a large and continuous timbered mat extended over the 500-ft. level for some 1200 ft. The stopes on the west end (at the air-shaft) were top-sliced down as far as the 655-ft. level, whereas those in the east end had only reached the 500-ft. level. Above the

FIG. 6. CORONADO ADIT AND INCLINE

west from the portal of the adit. In 1917 nearly all the Coronado stopes were west of the Matilda shaft, between the 700-ft. and 500-ft. levels. The 700, which is the extraction level for all the Coronado stopes, was the only one at that time which extended from the Matilda shaft (through the Coronado stopes and Horseshoe mine) clear to daylight, at the extreme west end of the vein.

During the month of August 1917, and for some time previous, the mine had been idle, owing to a strike in the district. As a protective measure, the company organized patrols, who visited the workings at stated periods during the 24 hours. At midnight, on August 19, the night patrol detected gas on the western end of the 655-ft. level, in the vicinity of the air-shaft, which is about 1500 ft. west of the Matilda shaft. The source of the gas could not be discovered, as there was no smoke. Later, smoke made its appearance on the 700-ft. level, near the air-shaft, and within a short time it came out in

timbered mat a large portion of the workings was caved and broken to surface. It was important therefore that the fire should be prevented from reaching the air-shaft, where the upcast air would carry it through the caved ground into the timbered mat beyond and make its extinguishment extremely difficult.

The first efforts to decrease the smoke and gas were made by means of doors, bulkheads, and small fans, in order that an attack might be made on the fire in the neighborhood of the air-shaft, approaching it from the east end of the 700-ft. tunnel, the main object being, if possible, to go up the air-shaft to the level above, and seal the fire that was progressing westward on the 655-ft. level. No attempt was made to reach the air-shaft from the adit on the extreme west end of the 700-ft. tunnel, as this was the natural outlet for the smoke and no electrical power was available at that end. Approach was also impossible from the upper levels, as the fire pre-

vented access on the 655-ft. level, and the air-shaft above this level was caved to surface.

However, before the smoke had been forced back sufficiently to permit of an approach, a cave took place in a stope immediately east of the air-shaft, and the burning rock found its way through chutes and filled that portion of the 700-ft. level beneath the stope. The removal of this caved material was necessary before further progress could be made, and, as it contained considerable pyrite and burning timber, it presented a hazardous undertaking. When water was first turned on, a large amount of steam, dust, and sulphur di-oxide arose from the waste-piles, making it almost impossible for the shovelers to approach. The water-lines had to be kept ten feet ahead of the men so as to flood the caved material before it was cool enough to be shoveled. A considerable amount of spiling and breastboarding had also to be done under the chutes from which the caved material had come.

When the work of getting through on the 700-ft. level was finally completed and the air-shaft reached, it was found that the fire had already progressed to this point and the air-shaft and several adjacent chutes had given way and caused further caving on both the 655 and 700-ft. levels. All hope of attacking the fire from above had then to be abandoned, and it was therefore decided to build bulkheads and flood the ground.

This was an ideal flooding scheme, for the reason that, as stated above, the workings extended along one continuous vein, having parallel drifts on the different levels, and it only required a few bulkheads to complete the reservoir. Two of these were constructed on the 700 (at the east and west ends of the level), one on the 655, and one on the 600 (both at the east end, as on the west the levels ended in solid rock). As all indications led to the belief that the fire had not progressed farther than 55 to 70 ft. above the 700-ft. level, it was apparent that only a comparatively small amount of water would be required. However, in order to make sure that any peaks of flame that might extend into the mat were extinguished, it was decided to raise the water-level about 120 feet.

After the bulkheads were completed, a little over two million gallons was pumped into this underground reservoir. Considerable difficulty was experienced at first in raising the water-level, owing to unforeseen conditions in the vein (through which the tunnel extended), at the point where one of the bulkheads was constructed; nevertheless, the water was finally raised 120 ft. above the 700-ft. level, which thoroughly drenched the lower portion of the timbered mat.

The water was then drained off, the bulkheads removed, and the levels prepared for stoping operations. Subsequent examination and later stoping showed that the fire had been completely extinguished.

Ten months later, on the night of June 17, 1918, three men were gassed while pulling ore from a shrinkage-stope on the 400-ft. level of the Coronado mine, over a quarter of a mile east of the place of the first fire. As a

lot of blasting had previously been done, it was thought they had been overcome by powder-smoke. Gas was noticed the following day on the 600-ft. level, about 350 ft. west of the shrinkage-stope mentioned. An investigation was made; although no fire was discovered, nevertheless there was considerable smoke. During the summer, from May to November, the air currents in the Coronado reverse daily and the shafts and small openings through the mat to surface are downcast the greater part of the day, whereas the main adit on the 1100 is an outlet. Bulkheads were therefore put in on the 600-ft. and 700-ft. levels, in order to prevent the gas from going into the lower workings. However, the smoke and gas kept increasing so rapidly that in a short time the workings had to be abandoned.

Blowers were put in operation on the 400, 500, and 700-ft. levels, to force the smoke and gas back and up through the mat and caved workings to surface. The fire was then located in a raise on the 600-ft. level, connecting with one of the top-slice stopes, but before any effective fighting could be done the surrounding ground caved.

As this outbreak had occurred over 100 ft. higher in the mat than the former fire, it was decided not to attempt to re-flood the workings, but to seal the stopes adjacent to the fire, put the remainder of the mine under pressure, and continue operating. The ventilating equipment that was immediately available, although inadequate for the task, was sufficient to force the gas back far enough to allow normal production to be continued, and 11 days after this second fire was discovered, the mine was again in operation.

On August 5, 1918, smoke was discovered in another stope on the 600-ft. level of the Coronado mine, some 150 ft. west of the fire of June 17. This stope was being operated on three shifts by top-slicing for the purpose of carrying it down rapidly in order to sever the timber connection extending through the mat from the point where the fire of June 17 occurred to the live workings beyond. The back of the stope and drift leading into it soon began to settle, which made it absolutely necessary for the men to do a lot of reinforcing and bracing of timbers before an effective attack could be made on the fire. Burning timbers dropped down the chute beneath the stope and set fire to the 655-ft. and 700-ft. levels. The smoke was so thick on these lower levels that the fire could not be extinguished before the ground had caved.

With such a large fire existing in the timbered mat, it was impossible with the inadequate ventilating equipment to continue operating with safety. It was therefore decided to seal the entire mine and admit superheated steam. Pipes were laid and an old boiler-plant on the surface was utilized. The superheated steam was carried into the fire-area on the 600-ft. level in the form of vapor, in order to reach the various peaks of flame that extended from the fire-stoppe. This was continued for about six weeks. On November 25, 1918, the mine was re-opened and examined on the 500, 600, and 700-ft.

levels, and while the large fire appeared to be extinguished, a raise on the 500-ft. level, about 300 ft. east, was found to be burning. The entire fire-area was again sealed and steam turned into the 500-ft. level. The finding of the fire above the 500 led to the belief that at the time of the outbreak of June 17, 1918, a number of fires

FIG. G. WEST YANKEE SHAFT, MORENCI

were started in different places in the mine, but owing to caved rock, smoke, and gas, it had been impossible to explore the 500-ft. level before, and consequently this particular fire remained undiscovered until the mine was re-opened on November 25, 1918.

JEROME DISTRICT

Fires have existed in the mines of the United Verde Copper Co. for over 22 years.* These fires were originally caused by friction, due to the caving of orebodies containing a large percentage of sulphur. There have been a number of outbreaks from time to time, necessitating the bulkheading of a large portion of the upper levels.

Various methods of fighting these fires have been tried and the management has finally decided to reclaim the ore in the fire-area by stripping the overburden with steam-shovels.

On January 20, 1917, a cave occurred in the 1407 stope of the small orebody of the United Verde Extension mine.

This ore was very heavy and contained a high percentage of copper and sulphur. In a comparatively short time the entire stope became hot and a fire ensued. It was then found necessary to design a temporary ventilating system that would clear the smoke and gas. Raises

had to be driven, the cave timbered and cribbed in such a manner as to prevent further movement of ground, while main gangways were established through the stope. After considering the different methods applicable under these circumstances, it was decided to excavate the caved ground by underhand stoping. Considerable patience had to be exercised in training the men to timber the stope thoroughly as the work progressed. After completing the first floor at the top of the cave, and filling with waste, another was started, and this plan was continued until not only the broken ore, but also the loose pyrite scattered around the stope had been removed. The greater the amount of pyrite and rich sulphides removed, the lower the temperature became, until there was a complete absence of gas and the heat had decreased so that working conditions were restored to normal.

In December 1917, a fire at the collar of the Daisy shaft of the same company destroyed several sets of timber. However, hose and water connections were soon available and in a comparatively short time this fire was extinguished. It was taken in time and resulted in only slight damage. Since then the first set below the collar, and connection to the fan on surface, have been made of concrete.

CAUSES OF MINE-FIRES

The usual causes of fires are defective electric wiring, neglected candles, heated bearings, blasting, spontaneous

FIG. 8. UNITED VERDE MINE, SHOWING SURFACE THAT IS NOW BEING STEAM-SHOVELED

combustion resulting from pyritic orebodies that have caved, and incendiarism.

Fires in surface-buildings have been the cause of many catastrophes underground. The fire is communicated to the shafts and thence to the workings. In recent years, however, steel head-frames and other fire-proof construction have come into general use and a convenient water

*Mine-Fire Methods Employed by United Verde Copper Co. R. E. Tally, A. I. M. E., Bulletin, Sept. 1916.

supply is usually available, so that the possibility of mine-fires from this source has been largely obviated.

During recent years there have been at least 35 active fires in copper mines in the South-West. Twelve of these were in shafts, while the remainder occurred in drifts, raises, and stopes. The causes may be classified as follows:

Candles	3
Defective electric wiring	5
Sulphide stopes	11
Incendiary	15
Unknown causes	1
	—
	35*

Fires in sulphide stopes were the cause of at least 31% of the above. These fires originated from the heat caused by friction in moving or caving ground, containing a high percentage of sulphur. Such fires are extremely dangerous on account of the gas that is given forth. Aside from the distillation products of wood, sulphur di-oxide is always present in large quantity, which adds considerably to the difficulty of fighting a fire.

When stoping is first commenced in an orebody of this character, the workings are just as cool as they are in a body of ore having no sulphur content, but after mining has progressed for some time, should the ground be allowed to settle or cave, the results of friction are indicated by a steadily increasing temperature until the stope becomes so hot that it sets fire to the timbers. These in turn set fire to the sulphur in the ore. The importance of selecting the proper method of mining an orebody of this character cannot be too strongly emphasized. As a general rule, no caving method can be applied, and as this ore is usually very heavy it must be stoped by taking out very small sections and immediately filling with waste. In this way only a limited portion of ground is left open at any one time, thereby minimizing the danger from caving, which is the principal cause of fire in sulphide ores.

Great caution should be exercised in operating stopes by the top-slice method. A fire that has once obtained a good start in the timbers usually forms peaks which extend so far up in the mat as to become inaccessible; and while the lower part of the fire may be extinguished, there is always the danger of these peaks of fire progressing through the caved ground along the top of the mat. For this reason, every mine in which the top-slice method is used should be equipped with mechanical ventilation, and fire-fighting plans fully prepared beforehand, so that should a fire start the section in question may be bratticed off immediately, put under pressure, and an attack made before the fire has an opportunity to get beyond control.

Aside from the active mine-fires described in this paper, there were at least five dormant fires, which were the result of filling old stopes with timber and pyrite

before the danger of sulphide fires was appreciated. Some of these required a great deal of development work and considerable expenditure before they were cooled sufficiently to prevent their generating gas, and thereby endangering the live workings.

Many writers have shown reserve in including incendiary among the causes of mine-fires, but a careful study of the origin of recent fires in the South-West shows that over 40% of them have had this sinister origin. Since this has become a definite cause, it is imperative that the fact be recognized and preparations made accordingly. A few companies have already realized this and have made adequate preparations to prevent such fires, principally by sealing their old workings, locking the exits and entrances to mines, erecting doors at shaft-stations, and resorting to mechanical ventilation in the newer workings. For instance, at one mine, separate water-pipes are laid parallel with the air-pipes, fire-doors are being built to separate the shafts from the workings, and also the different divisions from each other; a large number of bulkheads have been constructed to seal old workings; a system of fire-patrol introduced; helmet crews trained, and complete apparatus and fire-fighting equipment kept on hand. A second mining company, aside from installing a mechanical ventilating system, has adopted further preventive measures, such as placing water-pipes in the shaft, fire-doors to separate the different mines, removal of mule-barns from shaft-stations, and concreting of the main hoisting-shafts. Another large mine has an extensive system of fire-protection, which includes mechanical ventilation, sprays in the shafts, doors at shaft-stations, and a complete code of directions, specifying duties for everyone in the organization.

Other companies have realized the great importance of fire-proofing their main working-shafts (as well as making them downcasts), so as to eliminate the danger of fire in the shaft, and the possibility of any smoke or gas entering the live workings from this source. By making the working-shafts downcast, in the event of a fire underground, the men can then come out to the different shaft-stations into good air, and without fear of the gas overtaking them.

The old method of fighting fires was to make a dash into smoke or gas without any pre-arranged plan, keeping the entire crew in the most excitable condition and doing many things that were extremely hazardous and that really accomplished practically nothing toward extinguishing the fire. At times, helmet men were sent thousands of feet into gaseous atmosphere, when there was but a bare possibility of their ever returning. In one case, two helmet men out of five lost their lives under just such circumstances, without a single thing being accomplished. Another old-time method was to have men rush into gas to build a bulkhead, unprotected by helmets, and work two-minute shifts, then return to fresh air while two other men rushed in and took their places. There are cases on record where it took several days to build a bulkhead in this manner, which can now be con-

*This total does not include the numerous outbreaks in the United Verde mine at Jerome during recent years, nor the inactive fire-areas and dormant fires in other mines in Arizona.

structed within a few hours when mechanical ventilation is used in fire-fighting. In the former case, not only did it take much longer to build the bulkhead, but many men were overcome with gas and had to be rushed to fresh air, while the remainder of the crew were sick and suffered from headache and nausea when going off shift.

In fighting fires in shafts, care should always be taken to see that the men are first removed to a place of safety, before any water is turned down the shaft. When the men are out of danger, the most effective method of attacking the fire is to close the iron doors at the collar, and the doors at shaft-stations on the different levels, for the purpose of bringing the ventilation to a stop while water is turned on the fire from sprays placed at regular intervals down the shaft. Merely closing the iron doors

charcoal, even though not exposed to them for more than two minutes, while, incredible as it may seem, their companions escaped injury by simply holding their breath and walking a distance of ten feet into good air. The fall of rock down a raise, causing a tremendous air-blast, forces the heated and burning charcoal (which appears in the form of fine black dust), along the tunnels or drifts for hundreds of feet. When this combination is inhaled, the hot poisonous gas and dust destroy the tissue of the lungs. These air-blasts are frequently mistaken for explosions of carbon mon-oxide. This is an erroneous idea, as, so far, every case in the South-West has been the result of falling ground.

When exploratory work has to be done long distances through smoke and gas, mechanical ventilation is usually

FIG. 9. UNITED VERDE EXTENSION MINE

at the collar is not sufficient to hold the ventilation in check, as there is always a certain amount of leakage, and in such cases gas has been known to proceed along the main haulage-ways for hundreds of feet from the shaft. When water is turned into a shaft under these circumstances, if there are any men in the mine, in all probability there will be a good many fatalities. One instance of this kind has already occurred in which over 50 men lost their lives. This illustrates the necessity of installing fire-doors at shaft-stations as well as at the collar of the shaft.

One of the serious dangers accompanying the fighting of fires in mines is that of air-blasts, which are caused by caves following the burning of the timbers in raises and stopes. These may be frequent; their intensity depends on the quantity of material and the height of the cave. Great care should be exercised in work around a fire where caves are likely to occur, and frequent instructions should be given to remind the men of the serious results that may follow their being caught in the gas resulting from the air-blast. There are cases recorded where men have received fatal injuries by inhaling these noxious gases, in conjunction with minute particles of burning

employed to clear the atmosphere as far back as possible. As the workings are being cleared of smoke and gas by means of ventilation, great care is always exercised to prevent the fresh air from stimulating the fire. This is accomplished by the extensive use of bratticing. The brattices are moved ahead as the work of clearing the smoke and gas progresses. When the fire-area is reached, water is turned on through openings in the brattices.

This method permits the maintenance of a safety-station in the proximity of the fire, so that attacks can be made by men without oxygen apparatus. While helmet-crews are necessary for exploratory purposes, and, in exceptional cases, to complete work in certain places that cannot be ventilated quickly, nevertheless, the larger part of the work is done by men without oxygen apparatus, and therefore a far more rapid attack can be made on the fire.

The work of fire-fighting is frequently rendered extremely hazardous by the caving and air-blasts. In many instances, the warning that precedes these air-blasts is very slight, consisting either of a slight cracking of timbers, falling of cinders, or dropping of small particles of rock. Experience has shown that a man wearing a hel-

met, owing to his encumbrances, is not as sensitive to these signals and cannot make his escape as quickly as a man without the apparatus. It is therefore quite an advantage to be able to conduct as much of this dangerous work as possible in good air without the apparatus. Another advantage is that fewer men have been knocked out by smoke and gas as compared with those fighting fires in mines ventilated by natural means.

Still another consideration of great importance is the continuity of air currents in a definite direction, when mechanically controlled, as contrasted with the variable movements of the natural draft, which subject the miners to continual atmospheric changes, depending upon the season of the year and time of day.

The economy of mechanical ventilation is apparent when it is considered that the cost of fighting fires in mines where such systems are used ranges from 10% to 20% of that in mines using only natural ventilation. This has been proved in all the largest mine-fires in the South-West. Furthermore, a considerable number of fires have been extinguished by the use of ventilating systems before the fire had a chance to spread. This would have been impracticable had the ventilation not been controlled by mechanical means, as the smoke and gas would have been carried in every direction by the variable currents of air.

It has been demonstrated in a number of instances that with the use of mechanical ventilation, properly designed and carefully handled during a crisis, a mine in which a fire exists can be kept in continuous operation by controlling all the air that enters and leaves the fire-area, thus obviating long delays, large expenditures, and curtailment of production.

Mining in the Potosi District

A railway connects the city of Potosi with the main line of the Bolivia railway between Uyuni and La Paz. This branch line is 174 km. long and makes connection with the main line at the Rio Mulato junction, which lies 105 km. north of Uyuni and 441 km. south of La Paz. The Condor station on this line, at the point where the railway crosses the divide of the Cordillera de los Frailes, is probably the highest altitude reached by any railway line in the world, being at a height of over 15,800 ft. above sea-level. There are two trains a week between Potosi and Rio Mulato, which make the trip in a little less than 9½ hours. Passengers coming from Antofagasta, after leaving that port at 7:50 p.m. on Tuesday, reach Potosi at 7:34 p.m. on Thursday. The freight traffic of the Potosi district is divided between the Antofagasta and Arica routes, though most of it passes through the former port. The railway line which is being built in from Potosi to Sucre has been completed as far as Betanzos, a distance of about 55 km. Passenger service as far as Betanzos was started several months ago, but this line has not yet begun to carry freight destined for Sucre.

The Potosi district is essentially a mining region, and

whatever other industries exist are subordinate to this main interest. The mining industry centres about the famous Cerro de Potosi, although there are less important mines at other points outside the immediate radius of the city of Potosi. Silver and tin are the principal products of the Potosi mines, though copper, lead, antimony, and other minerals are also produced. Exports from the district during 1918 were as follows:

Mineral	Kg.
Tin:	
Barrilla (concentrate)	4,639,530
Bars	582,050
Wolfram	1,990
Silver	22,840
Copper	31,000
Bismuth	18,360

The Cerro de Potosi is a cone-shaped mountain about 2000 ft. high, situated on the outskirts of the city of that name. The Spaniards began to work its rich deposits of silver ore in about 1545, and during the colonial régime the enormous quantities of silver taken out of the Cerro, variously estimated at from \$1,000,000,000 to \$2,000,000,000, formed the principal basis of the mineral industry of the old viceroyalty of Peru. However, the Spaniards not only ignored the tin and other metals existing in the Cerro, but the inadequate methods used in mining and smelting prevented them from securing the full benefit of their labors, so that the dumps left from their workings still contain an appreciable quantity of metal. During the past few decades there has been a marked revival of mining in the Cerro, the present operators being comparatively new comers.

The most important interests in the Cerro are those belonging to Luis Soux, of French birth, who operates several mines in the Cerro and owns a smelter, the only one in Bolivia, which was built about 25 years ago, and in which he makes bars containing about 95% tin. He also sends out large quantities of tin concentrate (barrilla) and silver ore. About 1000 people are employed in all his workings. The second most important interest in the district belongs to Bebin brothers, also of French origin. These men have recently installed a new concentrating plant, where the tin ores from their mines in the Cerro are prepared for shipment in the form of concentrate. The equipment of this plant, which is the most modern of its kind in Bolivia, is of American manufacture. About five tons of barrilla, which runs from 55 to 60% tin, are turned out per day. Probably 400 employees are on the payrolls of the Bebins. Third in importance are the interests of the Anglo-Bolivian Mining Syndicate, Ltd., which is controlled by the Aramayo Francke Mines, Ltd., with important tin, silver, and bismuth mines in southern Bolivia near Atocha. This company works, among other mines, the old 'Real Socavon', which dates from early colonial times. Of secondary importance are the mining interests of Benavides, Cabrimonte, and Medinaceli.

Numerous small operators work one or two 'galleries' with the aid of a few Indians and sell their ore to the larger miners or to the regular buyers of ore.

Oil-Shales and Their Economic Importance

By MARTIN J. GAVIN, U. S. Bureau of Mines

*The twentieth century has often been spoken of as the age of petroleum, and from many viewpoints it can be justly considered so. Certainly the petroleum industry is one of enormous importance to this country, industrially, financially, and economically. The United States, however, at present producing over 60% of the world's total output of petroleum, is not producing petroleum at a sufficient rate to provide for its own domestic consumption. For several years this country has been importing increasing quantities of crude and partly refined oils from Mexico, and has been drawing heavily on domestic stocks of petroleum. Production in the United States is increasing, but it is not increasing at the same average rate as domestic consumption, nor is it probable that in the future domestic production will increase sufficiently to satisfy the demands of domestic consumption, but on the contrary, in the opinion of those best qualified to know, the peak in the curve of domestic production of crude petroleum will be reached in a comparatively few years, whereas the consumption of petroleum and its products will increase at a continually growing rate. This country, then, must turn, and as the increasing imports from Mexico indicate, is turning, to other sources than the crude petroleum produced in this country to make up the deficit between domestic production and domestic consumption of petroleum and its products.

The chief products of petroleum are motor-fuels, kerosene, fuel-oils, and lubricating oils. Of these, the increasing demand for motor-fuels, or gasoline, is perhaps the greatest, and that of fuel-oils probably next greatest. The ever-growing use of the internal-combustion motor, especially in automobiles and trucks, accounts for the first, and the increasing use of fuel-oil, chiefly for steam-raising purposes, accounts largely for the second. Lubricating oils are, of course, of prime importance, as machinery must be lubricated if it is to operate.

To compensate for the deficit in our supply of petroleum we can expect to draw on the enormous potential supplies of Mexico at an increasing rate, and by the use of new and improved processes of manufacture a greater percentage of the petroleum products for which there is the greatest demand will undoubtedly be obtained from petroleum. The more efficient utilization of these products, as for example, through the development and use of the Diesel engine and the gradual change in the design of our present internal-combustion motors, enabling them to use lower-grade fuels, will perhaps tend to relieve the growing shortage. Hydro-electric power, or

electricity otherwise produced, can be expected to take the place, to a certain extent at least, of fuel-oil installations on land. However, all these expedients have their practical limitations, and it is to be expected, therefore, that in the comparatively near future new sources of products similar to those now being derived from oil-well petroleum will have to be developed. As a matter of fact, some are already being developed.

There are possibilities of importance in the development of the production and use of benzol as a motor-fuel and other coal-tar products as Diesel-engine fuels and as substitutes for other petroleum products. There are also important possibilities in the commercial production of alcohol as a motor-fuel. In fact, blends of alcohol, benzol, and petroleum distillates are being marketed in the East at the present time as motor-fuels and are giving satisfaction in use. Taking all these considerations into account, however, it is the opinion of many that the oil-shales of Utah, Colorado, Wyoming, and Nevada, and possibly of other States, are extremely important as new sources of products similar to those now obtained from oil-well petroleum. These States contain enormous deposits of oil-shale, which by proper treatment yield gas, oil, and also, if desired, ammonia, of value as a fertilizer. The oil in many respects is similar to oil-well petroleum and yields products similar to those of petroleum.

Oil-shale has been worked in Scotland and France for upward of sixty years. In the former country the industry has been a successful one from a financial standpoint, especially of late years, although it is passing through a difficult period at present. The industry in France has not been nearly so successful as that in Scotland.

The success of the Scottish shale industry has been brought about partly by the development of cheap processes for treating the shales and the oils produced from them, but mostly by local conditions, such as competition only with high-priced petroleum products, low labor-costs, and the fact that the industry grew up in a densely populated region where a ready market for oil and ammonium products was available. A recent reorganization of the Scottish shale companies, combining them into one organization, is hoped to better the present condition of the industry in Scotland.

Oil-shale contains little or no oil as such, but it contains substances which when the shale is subjected to destructive distillation yield gas, crude oil, and nitrogen-containing compounds, notably ammonia, as well as the other products in small quantity and probably of unimportant value for the most part. Oil-shale as a rule must be mined much as coal is mined, crushed, and heated to a relatively high temperature in closed retorts, which may

*Presented by permission of the Director, U. S. Bureau of Mines, before the 13th Convention of the Utah Academy of Science, April 3, 1920.

operate continuously or intermittently. These steps are necessary to produce gas, crude oil, and ammonia, the last of which is in solution in the water obtained along with the oil.

The ammonia water is then distilled and the released ammonia passed into sulphuric acid, producing ammonium sulphate. The crude oil must be refined, much as petroleum is refined, to produce the various commercial products. The refining of shale-oil is more complex and in all probability more costly than the equivalent refining of petroleum. However, the shale-oils can be refined and can be made to yield many products similar to those produced when petroleum is refined. The oils produced from shale of this country will yield gasoline, burning oils, and paraffin wax, all of which when properly treated will undoubtedly be satisfactory commercial products. Whether the more viscous grades of lubricating oils, such as lubricants for internal-combustion motors, can be produced from shale-oil is doubtful, but it may be possible to do so. Little is known in this country as to the refining of shale-oil at the present time, and this statement can be applied generally to the possibilities and technique of oil-shale operations in the United States.

The development of an oil-shale industry to one of considerable importance in this country will require the expenditure of many millions of dollars and take a period of many years. Such development will require much research and technical study, and will require the services of trained executives and experienced technicians. Nevertheless, when economic conditions become favorable it is reasonable to believe that our oil-shale will be of great value as a source of oils similar to those now derived from petroleum. An idea of what large-scale development of the oil-shale industry involves may be gained from the consideration that to produce one barrel of crude oil from shale, on the average at least one ton of a tough rock must be mined, crushed, heated to a relatively high temperature, and finally the residue, amounting to about 75% of the original weight of the raw shale, must be discarded as valueless. The United States now produces over one million barrels of crude petroleum per day.

Our immense oil-shale deposits practically assure us that, come what may, this country will still have its own sources of petroleum products. We should never have to be wholly dependent on foreign countries in this respect. From another standpoint, the shale is also of great economic importance. The oil-shale, especially of the Rocky Mountain country, occurs in sparsely settled regions. Its development on a large scale means the bringing into these regions of a great number of miners and other laborers, often with their families, who will earn their living and spend their money in the same locality. Millions of dollars must be spent in erecting plants, developing mines, and the like, much of which will be spent in the States where the oil-shale occurs. The refineries will require sulphuric acid and other chemicals and supplies, which logically will be produced as near to the shale as possible, thus bringing in more capital and labor. Transportation facilities will be ex-

tended to meet the requirements of the operators, thus benefiting the regions now inadequately supplied in this regard. Prices of petroleum products in the regions contiguous to the shale operations can be expected to be relatively lower than they would be if similar petroleum products had to be shipped in.

It should again be emphasized, however, that development of an oil-shale industry to a scale sufficient to be of so much economic importance, will require much study, time, and money. The oil-shale industry is no business for the man of little experience and small capital. It may be compared with the development of the low-grade copper ores of the West, in that it is a large, low-grade, chemical manufacturing enterprise, requiring capital, time, and trained men. The investor in oil-shale operations should know that he will probably have to wait for a long time for a return on his investment and that returns in all probability will be conservative. In spite of this, the day of the oil-shale industry is coming.

The Color Bar on the Rand

Speaking recently as chairman of the Consolidated Mines Selection Co., Walter McDermott said: "Labor, as always, is the most important item, and it covers two separate difficulties, divided by the color bar. White labor is almost wholly some form of superintendence, and native labor constitutes the manual work on which all operation of the mines depends. There is a sort of common land between the two classes of workers in which native labor has proved itself capable of yielding valuable services; but it is a field of rather shifting boundaries, and the encroachment on it by natives is viewed by white labor with extreme jealousy always, and active opposition if it becomes at all marked. The natives are anxious for the more skilled work which carries higher pay. In the past the 'color bar' has been accepted without very serious question by the natives, but in the last few years constant contact with the effect of white-labor movements—in many of which the natives were sufferers, but gained no benefits—has had a marked educational effect, and colored labor has made progress in organization and in the adoption of the active proceedings which are seen to benefit white labor. In the recent strike of natives, the organizers of trouble adopted regular trade-union methods of picketing and rough handling of 'black-legs' who tried to work; and they thereby succeeded in promoting temporary uniformity of opinion. I believe the correct technical description of this sort of uniformity among English labor circles is "the solidarity of the proletariat", which is in itself quite a comforting phrase. There is a limit plainly within sight to the wages which can be paid in many mines working now on a small margin, and as the increase by war allowances has become permanent in effect, and as it is accompanied by higher cost of all material, and by additional outlay on the prevention and cure of miner's phthisis, the limit of possible working would have been passed already for some of the poorer mines if the premium on gold had not temporarily moved the boundary line."

The Bunker Hill Enterprise—XI

The Use of Electricity in the Operations of Mine, Mill, and Smelter

By T. A. RICKARD

One of the interesting features of the many and varied industrial operations performed in the mines, mills, and smelter of the Bunker Hill company is the use of electricity for divers purposes.*

Electricity was first applied at the mine in 1893, when an Edison bi-polar 500-volt D.C., 30-hp. hoist was placed in a winze below the Sherman tunnel. In 1897 this hoist was dismantled and the motor was employed to drive a fan for ventilating the Wood stope on the fifth level. Power was supplied to this motor through an Edison 500-volt D.C., 25-kw., generator driven by a 24-in. Pelton water-wheel. In 1896 the Bunker Hill company purchased the Edison three-wire 110-220 volt D.C. lighting system owned by Cheyne Bros. This plant was used to illuminate the town of Wardner; it operated two 20-kw. generators actuated by water-wheels on Milo creek at the lower end of the town. An auxiliary steam-engine had to be used during the dry season. It operated under a heavy expense and as soon as the Bunker Hill company gained possession the water-wheels were discarded in favor of a 2080-volt A.C. transmission line and transformers. The Cheyne brothers, Robert and James, were Scots. The elder was mill superintendent under Victor Clement and the younger was jig-man, becoming foreman later. During the riot of April 29, 1899, James Cheyne was captured by the strikers and shot by them. Robert returned to Scotland and died not long thereafter.

Horses and mules were used for hauling the rock broken in the Kellogg tunnel when it was started. In 1896 electric traction was introduced in the form of two General Electric 500-volt trolley-locomotives, each weighing $4\frac{1}{2}$ tons and each having a drawbar-pull of 1000 lb. The power was provided by a G. E. 50-kw. 550-volt D.C. generator connected by belt to a turbine taking water under a 56-ft. head from the mill-flume. The adit, or 'tunnel', was then 3000 ft. long and these electric locomotives were used in finishing the work. They still remain in use. The first ore was hauled out of the adit on November 9, 1902. Meanwhile another locomotive of the same type had been purchased, making a total locomotive capacity of 13 tons (three locomotives). At the present time the total locomotive capacity available at the mine is about 105 tons, besides 36 tons more at the smelter.

The track of the Kellogg adit has a gradient of 0.25% for half its length and 0.50% for the other half;† it is of

24-in. gauge and has 50-lb. rails. The outer half of the road-bed, where the ground is softened by oxidation and surface drainage, is reinforced with concrete. The ore-train runs at the rate of $6\frac{1}{2}$ miles per hour; it consists of a locomotive and 17 cars, each car when loaded weighing 4.4 tons gross. The locomotive has two G. E. type HM-801, 500-volt, D.C., motors, which can be used in parallel or in series; it weighs 8 tons and has a drawbar-pull of 4000 pounds. The cars are called 'Big Sams', a name given to them by Charlie Moffat, an old-time blacksmith, who supposed that the initial 'S' in the manager's name stood for 'Sam', these big cars having been designed by Mr. Stanly Easton for an increased capacity when he first took charge. They are 6 ft. $6\frac{1}{2}$ in. long and 3 ft. $4\frac{1}{2}$ in. wide, with hopper-bottoms. Each car contains 46.4 cubic feet; as the ore averages 14.3 cu. ft. per ton, the car holds 3.25 tons net. The car itself weighs 2472 lb. On the lower levels a smaller car is used; this contains 34 cu. ft. and weighs 1800 pounds.

On the lower levels, where the work of assembling the ore has to be performed, and where short hauls suffice, it is not practicable to use the trolley system. There the storage-battery locomotive does admirably. It obviates the necessity for bonding the rails and for maintaining a trolley-wire; it is capable of assisting itself if derailed, and, on account of the low voltage used (80 to 100), the maintenance of controllers and motors is much reduced as compared with the 550 volts ordinarily used by the trolley type of locomotive. On the other hand, the employment of the storage-battery for traction in the long main adit is considered inadvisable on account of the excessive battery equipment and the difficulty in placing it above the locomotive where the dimensions of the tunnel are restricted; if the battery is trailed behind the locomotive, the efficiency of the latter is reduced by the lack of weight on the driving-wheels and the necessity for pulling a dead load constantly. In low drifts cluttered with chutes or in places where the timbering is being repaired, men are likely to strike the live wire with their tools; under such conditions it is inconvenient and dangerous to use the trolley system.

The Bunker Hill company was prompted to employ the storage-battery locomotive on the working-levels for the reasons already cited and on account of the danger of transmitting a high voltage, such as is required for a trolley system, along small drifts where ore-chutes and low timbers project into the level. Fatal accidents in other mines, as well as in the Bunker Hill, served as a warning against any attempt to use the trolley below the adit-level.

*For my information I am indebted to Walter C. Clark, electrical engineer for the company.

†Where the grade is $\frac{1}{2}$ of 1% in favor of the load it requires exactly the same power to push the empty train up-grade as it does to bring the loaded train out.

The first storage-battery locomotive was used on March 3, 1913; it weighed $2\frac{1}{2}$ tons and made four miles per hour on a track of 24-in. gauge. It was made by the Jeffrey Manufacturing Co. and was placed on the 11th level. This locomotive was equipped with two sets of batteries, each of 63 cells, of the Edison A-4 type. One set was used on the day-shift and the other by night. These batteries were worn out after four years of continuous service and were replaced (in 1917) by two sets of 63 cells of the G-6 type of Edison battery. The second storage-battery locomotive was put to work in June 1913; it consists of a Westinghouse (Baldwin) $3\frac{1}{2}$ -ton machine equipped with 68 A-8 Edison cells and type V-50, 80-volt, motors. This locomotive has a running drawbar-pull of 2000 lb. and a maximum pull with sanded rail of 2300 lb. Its speed is $3\frac{1}{2}$ miles per hour. It replaced a 500-volt trolley locomotive on the 12th level. The third storage-battery locomotive was added on May 11, 1914, for the purpose of hauling tailing and sand for concrete road-work on the main street through the company's domain. The haul was 3250 ft. This locomotive was used in road-building until August 9, 1914, when it was placed on the 13th level for assembling ore. It was a General Electric 4-ton machine equipped with 72 A-8 Edison cells. It has a speed of 3 miles per hour and a drawbar-pull of 2000 pounds.

The fourth storage-battery locomotive was placed on the 14th level upon April 30, 1916; it consisted of a Westinghouse (Baldwin) machine equipped with two V-50† motors and 63 A-8 Edison cells; it weighed, with battery, $4\frac{1}{2}$ tons and had a drawbar-pull of 2000 to 2300 pounds.

The fifth locomotive is a General Electric machine, which was placed on the 10th level on April 26, 1918. It has 72 G-6 Edison cells and weighs $2\frac{1}{2}$ tons; it makes four miles per hour and has a drawbar-pull of 800 pounds.

The sixth is a Jeffrey machine of $4\frac{1}{2}$ tons, provided with 72 G-11 Edison cells. It began work in the mine in May 1919.

The storage-batteries arrive in trays, 8 by 36 by 15 inches, there being six to eight cells per tray. A battery-box, containing 72 cells, is placed on top of the locomotive chassis. The trays are taken into the mine on the electric train, lowered on the skip, and then assembled at the shaft-station, where they have remained in use on the level for one or two years before being brought back to surface for a general overhaul and thorough cleaning, previous to being returned to service for two years more.

A battery weighs 1800 lb; it is moved by means of a hoist operated by compressed air. If a suitable platform and track are available, the battery is rolled on and off by aid of castors placed on the battery-box at the mine. It may be added that with the later types of storage-battery locomotive, when only one battery is used for two shifts and the battery is not removed from the chassis for charging, it is customary to mount the battery-box on a swivel base, so that it can be turned at right angles to

the chassis for the purpose of exposing the motors and for facility in oiling, inspection, and repairs, without removing the battery.

The average life of batteries is four years. As they arrive from the factory they are filled with electrolyte. To charge the battery all that is necessary is to establish contact with the motor-generator set, which is placed centrally in the mine. On each level there is a sub-charging station equipped with variable-resistance and recording ammeters, so that each battery can be charged at the rate required by its storage capacity and internal condition. If a battery is sluggish, an excessive over-charge is given, and, in special cases, even a reverse charge may be given with beneficial effect. When a battery appears sluggish during the shift, a booster-charge may be given at twice the normal rate for a period of 20 to 90 minutes, in order that it may complete the shift without slowing down the train or causing the delay consequent upon the changing of batteries. This booster-charge is given at times when the train is standing idle or the motor-man is otherwise engaged, say, at lunch or attending to the locomotive equipment. The boost is given by increasing the volume, or amperage, of the electric charge to twice its normal rate, this being done by connecting the battery to the charging-station through the rheostat, or resistance-coils, thereby regulating the volume of charging current.

The specific gravity of the electrolyte changes, owing to evaporation of the water it contains, during the charging and discharging of the battery, so that it becomes necessary to add distilled water at regular intervals. Indeed, the healthy condition of the Edison battery is indicated in large measure not by the specific gravity of the electrolyte, as in the old lead cell, but by the amount of water required. If the proportion be excessive, this points to one of two conditions: either a deterioration of the electrolyte, or to excessive duty demanded of the locomotive on account of the bad condition of the track, caused, for example, by falls of rock on the rails, bad joints or curves, and the like. The water used for the batteries is obtained from Barnstead stills sold by Braun-Knecht-Heimann of San Francisco; these stills are heated electrically and have a capacity of a gallon per hour. One still is placed at each charging-station. Water for this purpose must be absolutely pure. For example, at the start use was made of water condensed from the exhaust-steam taken at about 500 ft. from the boilers of the heating system at the motor-barn. This water, of course, contained impurities, including grease, collected from a long and elaborate system of pipes; the result was a slow deterioration of the electrolyte and of the metallic plates in the cells. Thereupon it was decided to erect a still at the motor-barn near the portal of the adit. Water was delivered from this still to the batteries on the lower levels by means of large glass demijohns, which were carefully padded to prevent breakage, but they proved most unsatisfactory on account of the rough handling unavoidable on such a journey. Then water-bags of 5-gal. capacity were substituted, but these also were unsatisfactory on account of the contamination of the canvas and the con-

†This does not refer to the power, such figures as 'HM-801', 'V-50', and 'A-8' are merely serial numbers of identification as used by the manufacturer.

sequent penetration of mine-dirt into the contents. Moreover, it was found difficult to empty the bags into a suitable container previous to filling the cells. The next step was to place individual stills at each charging-station.

The filling of the cells is done expeditiously by means of a special nozzle equipped with an electric alarm, which

loosening the plates and separators to such a degree as to interfere with their proper action, and causing a steady decrease in the efficiency of the battery. A similar result ensues from a careless handling of the cover on the battery or the contact of steel tools over the exposed tops of the cells, thereby occasionally causing short circuits, the

THE 'BIG SAM' CAR

ings as soon as the liquid is at the proper level in the cell. This obviated any need for attempting to look into the cell, a practice that was found to be injurious to the cell itself and also to the men, because an explosive gas is generated and ignited by the open light used in making an examination. Such an explosion, even of a minor kind, results in a bulging of the sides of the cell, thereby

flash from which, like the open light during an inspection, ignites the explosive gas. The bulging sides tell the story. Mr. Clark and his assistant, M. J. Bottinelli, tried to rejuvenate batteries that had been in use for some time or had failed to recuperate under the customary treatment, such as a change of electrolyte, over-charging, and reverse charging. In order to accomplish their purpose,

they attempted to cleanse the cells, removing the accumulated sediment by means of agitation by hand, when the cells were only a quarter-full of electrolyte, and changing the electrolyte several times in each cell. When this method proved too laborious and expensive, they devised a mechanical agitator, which consisted of a cable-reel, 5 ft. in diameter, on the periphery of which 36 cells were clamped. As the wheel revolved the electrolyte flowed alternating from one end to the other of the cells, the ends being closed by rubber corks, so as to rinse the cell and wash out the sediment, the origin of which has not been determined. This practice has now been abandoned because the results did not justify the trouble. Instead, when a battery fails to respond to the usual treatment, it is returned to the factory, credit being received on a new set, this credit being based upon the manufacturer's 10-year guarantee. It is fair to remark that any battery subjected to the severe conditions necessarily incidental to work underground, at a distance of $2\frac{1}{2}$ miles from daylight, and not subjected frequently to the careful scrutiny of an experienced technician, is tried severely; it can hardly be expected to have the life normal to conditions on the surface. The Edison Storage Battery Co. maintains a service-station in charge of a competent engineer at Seattle. This engineer, Foster C. Gibson, takes a keen interest in the Bunker Hill operations and makes frequent visits to the mine, to advise and consult with those in charge in regard to the care and treatment of the storage-batteries, so that the most friendly and mutually helpful relations are maintained between the technicians of the two companies.

The electric haulage system of the mine is protected by block-signals operated by hand. The blocks vary in length, the first is a mile long and includes the outer straight portion of the adit, the other blocks are reduced to a minimum length of 300 ft. A 'safety first' sign is prominent at the point where the Tyler track branches from the main line. The noise of the train is magnified by the narrowness of the excavation and the echo from the rocky walls. In timbered ground the noise is considerably less; it is due to the gear-wheels of the locomotive, the friction on the rails, and the rattling of loose doors. The cars are equipped with springs. An empty train is the noisiest. The length of haul is about two miles. The heaviest train ever pulled out of the adit was one recorded on March 31, 1917; it carried 173,150 lb., or about 86½ tons, net. The weight of the entire train, including ore, cars, and locomotive, was 241,650 lb. or over 120 tons. The locomotive weighed 16,300 pounds.

The positive plates of the Edison battery consist of tubes, $\frac{3}{8}$ in. diameter, of nickel-plated sheet-steel, filled with alternate thin layers of nickel hydrate and flakes of pure metallic nickel. The tubes are mounted in nickel-plated steel frames or grids. The negative plates consist of thin rectangular pockets, $\frac{1}{2}$ in. wide by 3 in. long, of perforated sheet-steel, also nickel-plated, filled with iron oxide and mounted on nickel-plated steel grids. The electrolyte consists of potassium hydrate in water. The container is a steel can, corrugated and heavily plated

with nickel. The batteries now in use at the Bunker Hill consist of 72 cells of the G-11 type, with a 275 ampere-hour capacity. The weight of a cell is 26 pounds. Experience at this mine has shown that severe vibration or concussion does not affect the efficiency of the battery. Short circuits do not injure it. No buckling or grooving of plates has been noticed. Hydrometer readings are taken at intervals to determine whether the solution needs renewal after long use. No obnoxious fume or gas is generated when charging or discharging, although the slight amount of gas discharged immediately over the cell is inflammable, as stated above.

The first trolley-locomotive cost \$1500 f.o.b. factory; now a similar locomotive costs \$4000. The storage locomotives used to cost \$1140 to \$1500 before the War; now they cost \$3000 to \$6250, according to their size and type, the cheapest being the $2\frac{1}{2}$ -ton machine. The company now owns seven storage-battery locomotives.

An electric hoist is in use at the No. 1 or main shaft and a compressed-air hoist at the No. 2 shaft. Here I may interject the information that the main shaft is sunk at an angle of 50° and has three compartments, namely, two 5 ft. square and one 4 ft. by 5 ft. The No. 2 is sunk at an angle of 40° 30'; it has two compartments 5 ft. by 6 ft. and one 4 ft. by 6 ft. The No. 1 is extended by sinking and the No. 2 by raising. The No. 1 is used for hoisting ore, the No. 2 being devoted to the lowering of men, tools, and timber. Waste is rarely hoisted, of course; it is used for filling the stopes. The No. 1 shaft has two pockets to hold 100 tons, one is for ore and the other for waste from development work. This waste is hoisted to the adit and then dropped into chutes leading to the lower levels, from which it is drawn and taken to the stopes that are in need of filling. Both shaft-stations are concreted; the room in which the electric hoist stands, at the No. 1 shaft, is in solid rock, the walls of which have been whitewashed so as to improve the lighting. Looking from the auxiliary air-hoist at the No. 2 shaft through the rope-hole, one sees a second arch above the sheave, giving a cathedral effect, to which Mary Roberts Rhinehart referred poetically in an interview after her visit underground. The accompanying photograph shows how the impression was obtained.

At the No. 2 shaft a Hendrie & Bolthoff, 10 by 12 in., hoist is operated by compressed air. It has been in operation for six years and has given great satisfaction, I was told. It is run on counter-balance and has no ore-pocket.

The electric hoist at the No. 1 shaft was designed for duty from the 1400-ft. level, to raise a load of 7000 lb. of ore at the rate of 840 ft. per minute on a 50° incline in a skip containing 56½ cubic feet of ore. The normal cycle of operations from the 1400-ft. level is 13 seconds for accelerating, 93 seconds for operation at full speed, 5 seconds for retarding, and 18 seconds for loading below and dumping above. The hoist was made by the Allis-Chalmers Co. in March 1911; it has two cylindrical drums actuated by a 200-hp. 440-volt induction-motor, connected by gearing to the drum-shafting. The entire machine was sectionalized in order to permit of its being taken

through a 6 by 6 ft. tunnel. The total weight is 46 tons. The drums are cast-iron with a smooth surface 5 ft. in diameter and a 40-in. face, so that they can carry six layers of inch rope. The clutch is of the Lane friction type. The brakes are of the standard post type operating on wheels 6 ft. 8 in. diameter with 9½-in. faces. Auxiliary air-engines are used to operate both the clutch and brake; they are controlled from the platform. The control of the hoist is effected by means of a Cutler-Hammer multiple solenoid controller mounted in switch-board form. This switch-board controller in turn is controlled by a multi-speed master drum placed on the hoist-platform. The resistance units are of the cast grid type mounted in suitable frames. Sufficient resistance is provided for all the usual operations, with an additional section to be brought into play when operating the motor at 50% speed with 50% torque while handling men or for shaft inspection. An electrically operated oil-switch is controlled through a solenoid in connection with the master drum of the hoist; this connects and disconnects the primaries of the 2300-volt to 440-volt transformers at each trip, thereby obviating the no-load losses and magnetizing current when the hoist is idle.

The special feature of this hoist is the absolute control of the maximum demand at the time of acceleration. The time of acceleration and the maximum amount of current that can be drawn is controlled by the series relays; therefore the engineer cannot hasten the acceleration by rapid application of the controller. The following data indicate conditions developed during hoisting in balance:

Level	Hoisting distance on 50° incline	Pounds ore per trip	Kw.-hours per trip	Hoisting time in sec. per trip	Loading time in sec.	Time in sec. full time between bells
10	370'	7000	1.91	34	12	46
11	600'	7000	2.73	50	12	62
12	900'	7000	3.92	72	12	84
13	1170'	7000	5.05	92	12	104
14	1430'	7000	6.13	111	12	123

As an example of the duty performed by the hoist, I quote figures for the month of my visit, September 1919, as follows:

Number of tons hoisted from shaft (all levels)	24,740
Number kw-hr. consumed in the month (all hoisting including chippy work, etc.)	38,850
Average kw-hr. cost per ton of ore hoisted	1.57
Average cost in cents per ton of ore hoisted (electric power only, rate 0.625c. per kw-hour)	0.98c.

At the time when this hoist was first mooted the only electric hoisting in the district had been done at the Hecla mine, using a fly-wheel motor-generator. This hoist had proved successful, but costly; it came into service at the time when the Washington power-plant was just completed and the power company required that type of hoist in order to 'iron out', or average, the peaks in the consumption of electrical energy, and as the hoist was of a very expensive type, Mr. Clark was not in favor of buying one like it for the Bunker Hill. No straight-induction hoists of large capacity had been used in the Coeur d'Alene, but after a careful analysis of all the data available, Mr. Clark recommended the purchase of the Allis-Chalmers hoist as above described, but before placing it in position it became necessary to obtain the power company's consent to the connecting of such a hoist to their

electric system. The Washington Power Co. gave consent, being influenced favorably by the type of control selected. This provides for automatic acceleration and prevents peaks above a fixed level.

The accompanying diagram shows the cycle of operations between bells, when hoisting in balance from the 1400-ft. level. The net weight of ore is 7000 lb.; the speed of the rope is 840 ft. per minute; the hoisting distance is 1430 ft. on a 50° incline, the maximum current is 90 amperes, the minimum pressure is 2080 volts, the power consumed is 6.13 kw-hr. per trip. At the stroke of the bell the engineer opens the controller to its maximum capacity without hesitation and the automatic features of the control provide for a predetermined acceleration. In this instance it requires 13 seconds to accelerate

LOAD-CURVE OF ELECTRIC HOIST

from full stop to full speed, and it demands 315 hp. during these 13 seconds. The power consumed then drops immediately to 220 hp. and gradually diminishes during the period of hoisting—106 seconds—until it is only 137 hp., when the controller is closed and the loaded skip is carried by its own momentum into the pocket, completing the cycle in 111 seconds from the bottom to the dump. Twelve seconds are required to load the other skip, when the cycle is repeated.

This hoist is geared and therefore is noisy; it is a crude and rough machine compared with later designs made by the same and other manufacturers. It was chosen on account of its high efficiency and rugged durability, two expectations that have been amply fulfilled, as is shown by the kilowatt-hour cost per ton hoisted.

If it were a question of selecting a new electric hoist today, and if the matter of first cost were not critical, Mr. Clark would prefer, he tells me, a hoist of the motor-generator fly-wheel type, such as the Ilgner, because, although expensive, its smoothness of control and general efficiency recommend it; but for strict economy, and where looks don't count, he would again recommend the straight induction-motor type with automatic accelerating features like those of the hoist at the No. 1 shaft in the Bunker Hill mine. The automatic feature is admirable; the engineer has no control over the period of acceleration and therefore cannot establish unduly high peaks by excessive acceleration. When raising men, the

hoist operates at half-speed; this is done by slow application of the controller to half of the quadrant, registering the amount of resistance units that have been cut out.

I may add that at the time of selecting a hoist for the No. 1 shaft, the various types of hoist were passed in review. The use of compressed air was rejected on account of the length of the adit (two miles from the air-compressing plant), which would require the placing of compressors inside the mine close to the hoist or an expensive pipe-line from the outside, together with the reheating of the air before delivery to the hoist. The congestion of pipe-lines in an adit of such small cross-section would have been most objectionable. The first cost also would have been excessive, and the operating cost would have been high on account of the extra attendants. A suggestion was made by an engineering firm to use a synchronous motor directly connected to an air-compressor underground, to be installed with a series of small air-receivers (small on account of the dimensions of the adit) to supply air for an air-operated hoist, but the idea was rejected on account of the excessive outlay, the cost of attendance, and the amount of money to be invested in expensive apparatus that could not be removed from the mine in case of a temporary shut-down, and the rapid deterioration of such machinery if left in the mine during a period of idleness, and the probability of the receivers leaking by reason of the constantly varying pressure and temperature caused by the erratic demands of a hoisting-load. The Ilgner type of hoist was rejected for many of the same reasons, such as excessive first cost, inability to remove such parts as would suffer during periods of idleness, and especially the probable damage to the direct-current motor-commutators that would be caused by excessive 'sweating', whereas the hoist selected would raise the ore as cheaply as, if not more cheaply than, any other hoist available; and on account of the moderate sum of money invested the hoist need not be expected to operate beyond a moderate capacity, so that another hoist could be purchased advantageously in case it were demanded by future requirements; in short, it was deemed wise not to look too far ahead. The pumps in the mine are operated electrically. The new pumping equipment includes four centrifugal Cameron pumps of the turbine type, one each of three-stage, four-stage, seven-stage, and ten-stage. They make 1800 r.p.m. and have proved most satisfactory. As successive new levels are opened up, the flow of water increases until the ground overhead has been drained of its free ground-water; after that there is a steady seepage, so that a graph of the water pumped from the mine shows peaks at regular intervals coincident with the opening of new ground and a constant increase with depth due to the drainage of a steadily widening area.

I noted three or four carborundum wheels driven electrically. One stone was fine and the other coarse, each had a diameter of one foot; together they consumed about two horse-power. The use of these grindstones underground saves much time; in 10 or 15 minutes one machine does the work of two men, one to turn the stone and the other to hold the axe for approximately an hour.

The accompanying photographs explain themselves.

On the first page is shown the automatic tell-tale device that trips out the motor when any loose end in the rope sticks out. The device is shown in position; the end is electrically connected to the trip-coil fastened on the oil-switch. Two illustrations show the shaft-station with its concrete arches.

(To be continued)

Mining in Queensland, Australia

The mineral production of Queensland, Australia, last year was valued at £2,472,000, which was £268,700 less than during 1918. This decrease was due, not to declining resources except as regards gold, but to the great reduction in prices that followed, early in the year, upon the release of large quantities of metals, that had been held in reserve by the British government for war purposes; to a great scarcity of explosives; and to the existence of drought conditions for some time. In late years there has been an expansion in Queensland's mineral output apart from gold; and, prices having gradually recovered themselves in the course of 1919, the production of the last quarter of that year was higher than for the corresponding period of 1918.

Still further proof that the large northern State of the Australian commonwealth was recovering from its 1919 set-back in the output of industrial metals is afforded by the returns for the first quarter of 1920, which have just been published and which amount to £602,270, a comparative increase for the three months of no less than £351,360, or of 58%. In May, however, a disquieting effect was produced by copper dropping to below £90 per ton and tin to £270. More copper is now produced in Queensland than any other metal. The principal copper mines are in the Cloncurry district, over 500 miles from the coast at Townsville; and in this remote district, where the conditions of living are not alluring, the cost of production is high. The manager of one company has stated that it can now produce the metal at a cost of £61 per ton, which should give a handsome profit even at the present price; but the other big companies of the district, whose mines are not so rich or easily worked, had to shut-down in 1919 when copper dropped below £80, and will no doubt have to do the same again if quotations reach that level.

TWO MINING COMPANIES, the Finland Copper Co. and the Salla Mining Co., have bought some large deposits of copper ore which have been discovered in Kuolajarvi Parish in the Oulanka River valley in northern Finland. Geological examinations have shown that the copper near the surface is rich, and if diamond-drilling is used it probably can be ascertained whether mining on a large scale will be profitable or not. The directors of the companies have applied for a Government subsidy for this purpose, as security for which they offer shares of old stock at a nominal value of 200,000 Finnish marks. There are also rich veins of pyrite in the same place, apparently amounting to several million tons. Diamond-drilling will show the depth of these veins.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ALASKA

ACTIVE DEVELOPMENT AND PROSPECTING ABOVE HYDER.

HYDER.—The season's work has been well under way in the Portland Canal district for some weeks. With the snow gone and prospectors and miners in the hills the towns of Hyder and Stewart are almost deserted. On the properties along the Salmon and the Bear rivers activity prevails. The only notable new discovery is on the Georgia river, a few miles below Stewart, where a number of gold-bearing claims have been recorded. Sam-

COLORADO

NEW REDUCTION PLANT AT BOULDER.

LEADVILLE.—Operations have been resumed on the Collins group of the Golden Calf Mining Co. in Sayers gulch. Denver people have secured a bond and lease on the property. Aspen men are operating on the Ruby property in Lincoln gulch, following a long period of inactivity. The mine produced high-grade ore when last operated. South of Sayers gulch, Leadville miners are developing a promising orebody on the Tellurium lode,

FAIRBANKS DISTRICT, ALASKA

ples indicate that there is some rich ore and that the showing warrants development. The Marmot river also is being prospected and promising claims have been located. Development work is continuing on all the better-known mines and prospects and road construction is in progress to assist in the opening of the mineral region. The Unicorn group is to be drilled, a contract having been awarded to Lynch brothers, of Seattle, and F. P. Stewart has returned to the camp to supervise plans for opening the Mountain Boy group of Crown-granted mineral claims. He is a pioneer of the Portland Canal district, being credited with directing the attention of Sir Donald Mann to the possibilities of the district. Shipments are being made regularly from the Premier mine, and prospecting and development by diamond-drilling are proving up additional ore.

owned by W. E. Wright of Twin Lakes. The ore is rich in gold. The Burge group on the north slope of East Red mountain is being developed by a tunnel now in 1200 ft. The formation is rhyolite but no vein has yet been cut. Gouge of clayey matter contains pyrite carrying some gold.

BOULDER.—The Tungsten Products Co. is installing a chemical reduction-plant for the treatment of radium-bearing ore at its plant in this city to be completed during August. The ore to be treated is mined at Gateway, on the western slope. It is claimed that the uranium and radium will be recovered and the mill will be equipped to handle in addition tungsten and vanadium. The tungsten mining industry at Nederland in Boulder county is at this time practically at a standstill.

GEORGETOWN.—T. B. Burbridge of Denver, operating

the Jo Reynolds and American Sisters mines under bond and lease, is shipping a fair grade of ore obtained from development work, and is reported to have netted \$5000 in the first six months of 1920. Sub-lessees are also shipping. The Utah Copper Co. is reported to be financing the development of the Alice placer in this district. The Pennsylvania group is again active and will be developed by Eastern interests. The Canadian Syndicate is operating the Gem Mining & Milling Co.'s group near Idaho Springs, with W. E. Renshaw in charge. Ore-bins have been constructed at the Mount Kelso mines, and cabins are to be built to accommodate miners during the winter months, as continuous operation is planned. The group is developed by a tunnel. Ore has been opened on the main vein and shipments will start shortly.

CRIPPLE CREEK.—The test-drilling in the north end of the district has reached the 800-ft. point, with the core of the drill still showing nothing but granite. The rock is much harder and the two shifts are advancing about 20 ft. per day instead of 40 ft., as recorded for the first 500 ft. Lessees on the third level at the Lee shaft of the Isabella Mines Co. have installed an air-hoist and are hoisting ore from the vein recently opened. The ore is sampling one ounce in gold, and, as the vein or dike is fully 12 ft. wide, ore is made rapidly. One round of machine-drilled holes breaks more than the shovelers can handle on one shift.

TELLURIDE.—The mill of the Colorado Vanadium Co. is running steadily on vanadium ore from the Sawpit district and there is a good market for all ore mined. A recent shipment to the plant of the Ore Products Co. at Denver, from the Donegan property at Sawpit, netted the shipper nearly \$1000 for a 26-ton carload.

SILVERTON.—Machinery and equipment for the Martin Mining & Power Co.'s group of claims in the Picayune basin near Eureka, has been shipped to Denver and has been hauled to the property for immediate erection. Development on a large scale is planned. Sam Heidel, owner of the Mazeppa group in the South Mineral section of the San Juan, is mining a good grade of ore, in a tunnel driven to cut the Mazeppa vein at greater depth than the shaft workings. Shipments will shortly commence. Denver interests have purchased the Bandora group in the South Mineral section for a consideration reported to be \$100,000. A large tonnage of ore is blocked out and a milling plant will be constructed for local treatment of low-grade, according to the present plan. Ore of shipping grade will be consigned to the A. V. smelter at Leadville.

OURAY.—Mines in the Red Mountain, Sneffles, and Bachelor districts have been examined and samples forwarded to the Golden School of Mines for testing. Experimental tests are in progress at Golden to determine a satisfactory process for treatment of these low-grade complex ores. A discovery on an unpatented property, immediately adjacent to the Paymaster mine in the Iron-ton section has been made by James Davis, well known prospector of this city. A 4-ft. vein, believed by Davis to be

the extension of one of the rich Paymaster veins, has been cut. Assays were high enough to warrant Davis shipping a trial lot to the smelter.

IDAHO

POPE SHENON PROPERTY MAY CHANGE HANDS.

SALMON CITY.—An offer to purchase a controlling interest in the Pope Shenon Mining Co. on the basis of \$2 per share for the stock has been submitted to the directors of the company. It is believed that the offer is made on behalf of large Eastern copper interests. The company is capitalized for 1,000,000 shares. Most of the stock, of which slightly more than 800,000 shares has been issued, is owned by Salt Lake City people who financed the development of the property and construction of the mill. A volatilization mill was completed recently, having a capacity of 50 tons per day. The offer provides for an option on not less than a controlling interest, the option to permit a 30-day period in which to survey the property, during which time the company would continue operations. At the end of 30 days the holders of the option would take over the operation of the mine for further development, but would ship no ore. The development work is to occupy a period of five months. At the end of that period, should the option be exercised, a payment of \$500,000 would be made and the balance would be paid six months later. While the offer provides that controlling interest be acquired, it is desired to purchase the entire outstanding stock. The directors of the company have authorized R. H. Winder, president, to appoint a committee of three to investigate the proposition. The new mill was shut-down recently, following its initial test-run, to repair the damage done to the Cottrell electric-precipitating plant by fire. These repairs have been completed and the mill is again in operation. It is stated that there is approximately 100,000 tons of ore in sight in the mine, and the work of connecting various tunnels and raises is now under way.

MICHIGAN

CONTRACT LET FOR RE-TREATMENT-PLANT FOR TAMARACK SANDS.

HOUGHTON.—Calumet & Hecla's success with its 'reclamation' plant, which at present is yielding at the rate of 15,000,000 lb. of refined copper per year, is reflected in the awarding of a contract to the American Bridge Co. to erect a complete plant for the treatment of Tamarack sands. The contract, it is understood, involves the expenditure of \$1,000,000 for buildings and equipment. The new venture will be a replica of the Calumet plant, for it will include re-grinding, leaching, and flotation, and in size will equal the C. & H. plant. The site, now occupied by the old Tamarack mill, is being razed rapidly, and as soon as possible foundations will be put in. Because of the immensity of the project it is not likely that steel-construction work will begin until fall and more than a year will elapse before the plant is completed. The awarding of the contract bespeaks Calumet's faith in

the Michigan copper country and its full appreciation of the development of metallurgical processes. The Tamarack sand contains, it is estimated, from 15 to 40 lb. of copper per ton and its treatment will afford an excellent profit.

Quincy recently hoisted a 'mass' weighing 24 tons. This came from No. 2 shaft, which last year produced 1290 tons of mass copper. Incidentally, in the stope from which the mass was removed, another of still greater dimensions was uncovered and it will be brought to surface within the next thirty days. The first mass was 8 ft. long, 4 ft. wide, and slightly more than 4 ft. thick. It was so cumbersome that it was necessary to cut it into three pieces in order to get it into a skip. Acetylene torches were used for the work. In the old days such a task would have required weeks, for hand-chiseling was the only method known for cutting it. The mass came from the 82nd level.

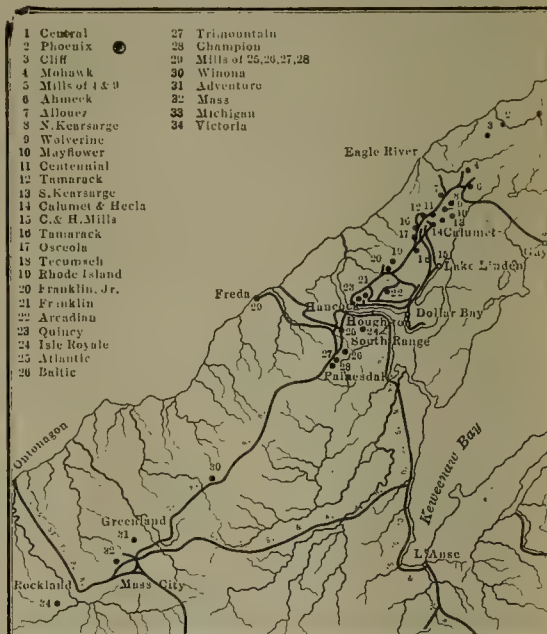

Baltic's sub-shaft, which will connect No. 2, 3, and 4 shafts, will require more than a year for completion. It is being driven at the bottom of No. 3 shaft on either side, and will connect on the 33rd level of No. 2. When complete, all hoisting for No. 3 will be done through No. 2, and considerable expense thereby will be avoided. Baltic's operations have been carried down to a depth of about 3900 feet.

The Mayflower-Old Colony south drift, which perhaps is the most important work in the exploration program, is breasted in a mixture of trap and vein-rock and is still going forward. In the north, the cross-cut still proceeds eastward, while the raise in the west cross-cut has penetrated some vein matter, with characteristics of the Mayflower formation. Mayflower feels the shortage of men to some extent, for many miners have gone to their farms and will not return to the mine until after the harvest.

Seneca's third and fourth levels, north, are producing rock of slightly better quality than for the past three weeks, with the third level drift at a point 469 ft. from the shaft and the fourth, 412 ft. from the shaft. The south drift on the third level, which reached the Ahmeek boundary a week ago, was in comparatively rich ground for almost its entire distance, and the fourth level, south, also is yielding good rock. The south drift on the fourth level is 260 ft. from the Ahmeek limits, which will be reached at 430 ft. The shaft has about reached the depth at which the fifth level will be holed-through and the forms are being installed for concreting the floor. When the concrete is poured and set, sinking will be resumed in order to put the raise up through the floor of the level. In the meantime it will be necessary to cross-cut to the lode. The concreting of the shaft will in no wise interfere with operations on the third and fourth levels, for the shaft already has been concreted from the fourth level upward. Little rock is being stamped of late, due to the labor shortage, and it is accumulating until sufficient quantities are available to warrant a mill-run. Gratiot's thirteenth-level drift, south, reached a point 506 ft. from the shaft on the 19th of the month and is

going forward rapidly. The ground for the past week is described as favorable.

Apart from the order for France, Calumet & Hecla has caught up on its orders, and shipments of metal practically are at a standstill, except for an occasional carload that goes to Kenosha, Wisconsin. Quincy's shipments are negligible and comparatively small quantities are being shipped by the Copper Range and Stanton groups. The Calumet order for export calls for billets and wire bars only, hence three weeks will be required to turn it out. Of 1500 tons that left early in the week for domestic consumers, Calumet's portion was 700 tons. In addition to its refined-copper shipment,

MINES IN THE LAKE SUPERIOR COPPER REGION

Calumet ships about 120,000 lb. of copper oxide per month.

The announcement that steps have been taken to provide fuel for the North-West was received with pleasure here, for it ensures winter coal for those mines that can afford to pay the high price. In some quarters a decline is looked for, but unless the drop is material it is certain that treasury surpluses will have to be drawn upon. The Copper Range mines, to illustrate, consume from 75,000 to 80,000 tons of coal per year and at present prices, \$10.50 per ton, the increase will mean upward of \$500,000 for this group alone.

MONTANA

NEW OREBODY OPENED IN THE FLOHART MINE.

NEIHART.—The Hartley mine is again in the list of regular producers. From the bottom of the shaft at the 300-ft. level, drifts have been driven on the vein and stopes have been opened 50 ft. in each direction from the

shaft. It is planned to open up more stoping-ground and double the present production.

The newly opened shoot at the Flohart mine has the characteristics of an extensive high-grade orebody. The present development consists of carrying ahead all the levels from No. 1 to No. 5 with a series of raises and chutes, so as to bring all the ore out of No. 1 tunnel to the ore-bins above the railroad track. The 500-ft. shaft will be drained to the 200-ft. level where the old workings will be explored; 20 men are employed at the mine. This mine has been operated intermittently for the past 30 years and is credited with a production of about 4,000,-000 oz. of silver.

HELENA.—Considerable development work is being done on the Jawbone property. Machine-drills have been adopted, making progress in tunneling and cross-cutting more rapid. Metallurgical tests on the ore are being made to determine the concentration method to be adopted for the mill that is to be erected. Gold and silver are the chief metals.

PHILIPSBURG.—The mines of this district are now producing 500 tons of manganese ore and more than 400 tons of silver ore daily. About 1000 men are employed at present in the district.

DEER LODGE.—The Champion mine of the Butte-Jardine company is making regular shipments of high-grade ore to the Washoe smelter at Anaconda. Work on the new mill is progressing satisfactorily. Recent development in the mine includes an 11-ft. winze in rich ore, and a tunnel 130 ft. on the orebody. Smelter returns on the last shipment gave 72.6 oz. of silver and \$4 in gold per ton; 43 men are employed at the mine and mill.

NEVADA

NEW REPORTS FROM DIVIDE.

COPPER CANYON.—The Homestake Consolidated Placer Mines Co., operating on the Guy Davis and Homestake claims, has finished sinking shafts and is preparing to start washing gravel. In April these claims were awarded to the Homestake Consolidated by the United States Supreme Court after years of litigation. There is little water near the claims, but by re-using the water it is thought the supply will be ample. More than five ounces of gold was recovered recently from one yard of gravel. The company has purchased 11,000 ft. of pipe to carry water to the claims. The work is in charge of William Forman, of Tonopah, who aided George B. Thatcher, formerly attorney-general of Nevada, in the court actions. The claims originally were held by the Glasgow & Western, an English exploration company, as lode claims. They were located as placer claims in 1913 by two miners, and when the locators disobeyed an injunction secured by the Glasgow & Western they were put in jail and remained there until their plight was brought to the attention of Thatcher, who took their case without charge and secured their release. One of the men, Guy Davis, interested others and the claims were again located and work was started, only to be stopped by

a second injunction. Davis took his case to Thatcher, who interested Forman, and in return for a share in the ownership of the claims the two attorneys went into court and secured a verdict in their favor on the ground that mineral in place had not been found on the claims. The case was appealed to the Circuit Court, which reversed the verdict. Thatcher and Forman then appealed to the United States Supreme Court and won their case after all of the locators had lost confidence and had sold out to friends of Thatcher. The claims cover what engineers say is the richest placer ground in the country.

IONE.—Robert B. Todd of Reno has financed in New York the construction of a 50-ton mill at the Star of the West, 20 miles north of Ione, in northern Nye county. The Star of the West is an old producer of silver-lead ore that has been re-opened by the cleaning of three tunnels and by work from them. Ore assaying \$20 for a width of 7 ft. has been found in surface trenches and assays of \$7 to \$18 have been secured from 6 to 10-ft. widths in the tunnel-workings. The lowest tunnel is 350 ft. long and it is to be continued 800 ft., or well into the San Francisco claim.

EUREKA.—The Prince is preparing a shipment of high-grade ore from the 140-ft., or bottom, level, where the shoot is 3 to 4 ft. wide. Some of the ore being saved assays more than \$200 in silver and gold in the proportion of 1 oz. gold to 50 oz. silver. The drifts on this level are in a shoot from which good shipments were made at the surface. All of the work on the Prince in former days was done at or near the surface, most of the production being made from a depth of less than 50 ft. The output from these workings is estimated to have been nearly \$750,000. The Croesus is shipping \$80 ore regularly, most of it being mined 1500 ft. north of the Catlin shaft, on the 400-ft. level. The Holly is shipping \$75 ore at a rate of 50 to 75 tons weekly from the 400 and 500-ft. levels. Sinking of the shaft from 450 ft. has been started. Shipments that net the company more than \$5 per ton continue to be made at a rate of 50 to 75 tons daily from the 900-ft. level of the Locan shaft of the Ruby Hill Development Co. There is estimated to be 50,000 tons blocked out. Sinking of the shaft from 1200 ft. has not yet been started. The Climax is preparing a shipment of ore saved in driving the Mabel L. tunnel, which is now well into the Deadbroke claim. No stoping has been done. There is a 3-ft. width of ore of shipping grade, with a 6-in. seam that is rich, in a 70-ft. winze at the 1500-ft. point in the Eureka tunnel of the King. An air-power hoist has been put in place and the shoot is being explored further.

DIVIDE.—A drift in the main vein of the Tonopah Divide near the Gold Zone line and on the fifth level has exposed 2½ ft. of 158-oz. ore. Rich ore also has been found in new work in the main vein on the third level and the main south-east drift on the first level is being continued in a full face of 70-oz. ore. According to reports it is probable that there is good ore for 150 ft. beyond the present face of the drift on the first level, as a raise this distance south-east, from the second to the

first level, is in ore. This raise was driven 105 ft. in good ore. It has been learned from an authentic source that the distance between the point where the main south-east drifts on the third, fourth, and fifth levels were turned from the main vein, and the Zone line, is more than 400 ft. These reports indicate that the main vein has not been explored for this distance. The ore recently found on the third and fifth levels is in drifts from cross-cuts driven to the main vein from the workings made by the former management. The Victory has resumed sinking the winze from the present depth of 360 ft. An electric

UTAH

FIRE DESTROYS SAMPLING-MILL AT THE MURRAY SMELTER.

SALT LAKE CITY.—Fire, thought to have originated from a burning cigarette, destroyed sampling mill No. 4 of the American Smelting & Refining Co.'s smelting plant at Murray, seven miles south of here, on July 26. The property loss is estimated at \$50,000. The mill was built about 12 years ago, and was the last of a series of four sampling mills, being adapted to the handling of ore that could not be sampled in the other three mills.

MECHANICAL VENTILATION IN THE SPECULATOR MINE AT BUTTE

hoist is being used and the winze will be continued another 100 ft. One carload of ore assaying 30 oz. silver and 0.25 oz. gold has been shipped from the 310-ft. level, from which the winze was started, and 100 tons of the same grade is ready for shipment according to reliable advice. Only low-grade ore, assaying \$8 to \$10, was found on the 360-ft. level. The shoot is 60 ft. long and 3½ ft. wide on the 310-ft. level.

CARSON CITY.—The Comstock Superior Co., operating in North Carson field, is preparing to sink on the junction of a cross-vein with the main lode. Several cross-veins have been found and the main orebody traced the full length of the group. Sinking is progressing steadily at Nevada Protective.

PARK CITY.—Mining operations have been resumed at the Three Kings property, following several months of exploration work with diamond-drills, which was done for the purpose of locating known ore-bearing lime beddings, according to P. J. Mackintosh, general manager. The drilling work furnished information of value in guiding mine development. A further increase was made in ore shipments from this district during the week ending July 24, when 2349 tons was shipped, as against 2267 tons for the previous week. The Ontario Silver shipped 911 tons; Silver King Coalition, 645 tons; Judge M. & S., 364 tons; Daly West, 170 tons; and the Naildriver, 165 tons. The Judge smelter shipped 94 tons of premium spelter.

BIG COTTONWOOD CANYON.—The stockholders of the Reed's Peak Mining Co., at a special meeting, unanimously voted to consolidate the property of the company with that of the Big Cottonwood Consolidated Mining Co., adjoining the Reed's Peak to the south. The new company is to be called the Reed's Peak Consolidated Mining Co. The property consists of an attractive group of 32 claims, located in the south fork of Big Cottonwood canyon, one-half mile north of the Cardiff mine and 22 miles south-east of Salt Lake City. The new company starts out free of debt, with \$8000 cash in the treasury, and with ample equipment in the way of tools, machinery, mine buildings, cars, and track. The portal of the Reed's Peak tunnel is but 12 miles from the Murray smelter. It is the intention of the management to begin operations immediately.

Conditions in the Cardiff mine are reported as excellent; an average of 50 to 60 tons per day of silver-lead ore is being shipped, that averages about \$55 or \$60 per ton. Five teams are engaged in hauling the ore down the canyon.

MILFORD.—Three lessees are mining exceptionally high-grade ore from the 'Wild Bill' mine, which adjoins the Cedar Talisman property; the last car of ore shipped netting \$4000 after payment of all charges, including royalty. The shipment averaged 61% lead and 38 oz. silver per ton. The property was opened by an incline shaft, but the company stopped operations before ore was found. The lessees sunk a short distance in a winze from the shaft before cutting high-grade ore. Mine development is increasing in Beaver county. J. M. Reynolds, who financed the Capitol company, which is now developing its property, has recently been successful in financing the old Humboldt group. Equipment has already been installed on the property and shaft sinking started. At a depth of 35 ft. a promising vein was struck, from which high-grade samples have been taken. It is the intention to sink this shaft to the 500-ft. level.

At the old Monitor property, the new lower tunnel has almost reached a north-south fissure that has enriched bedded deposits, which furnished good shipping ore in the upper levels of the mine. The tunnel has been driven 250 ft. and is about 40 ft. from its objective. Small seams of high-grade ore have been cut, which have assayed as high as 52 oz. in silver and 63% lead. William Gore, president and manager of the property, is well satisfied with the progress being made.

AMERICAN FORK CANYON.—Ore was found recently in a raise from the Holden tunnel which is being driven to open at depth the orebodies mined near the surface in the Live Yankee, Silver Wave, and Bellerophone properties. This is the first prospecting at great depth in this part of the district and is of importance on that account. The Holden tunnel is being driven by the American Leasing Co., controlled by C. B. Ferlin, former superintendent of the Pacific mine; the leasing company operating the three properties named, under a lease. In the early days, some of the richest silver ore found in this district was mined in the Live Yankee property. The ore was found as

large boulders of galena, lying in the bed of a stream which follows an east-west fault fissure. Much of the early-day mining in this part of the camp was done by A. L. Holden, later associated with the United States Smelting Co., and Mathew Cullen, of Salt Lake City, who were pioneers among Utah mining men. The American Leasing Co. developed considerable milling ore in the upper workings of the old properties and then built a small concentrating mill. The milling ore developed at a point 185 ft. above the Holden tunnel has been opened from 8 to 15 ft. in width.

EUREKA.—The suit of the Tintic Delaware Mining Co. against the Salt Lake, Fillmore, and Kanosh Railroad Co. has been decided in favor of the plaintiff. The suit was instituted to recover \$5000 and interest on money alleged to have been advanced to the representatives of the railroad company for the purpose of assisting in the building of a railroad from the Salt Lake Route in Millard county to the Deseret Mountain mine and other properties in the West Tintic district.

Walter Fitch Jr., mining contractor, who is sinking the new shaft at the Chief Consolidated mine, states that a depth of 1440 ft. has been reached and that the formation is changing. It is understood that the shaft is nearing the lime, as the formation is loose and large boulders of lime are making their appearance. This loose formation will necessitate using solid concrete lining instead of hollow concrete forms, such as were used in the upper part of the shaft. Excellent progress has been made in the sinking of this shaft, an average of 61 ft. being made each month. The shaft will be sunk to the 2000-ft. level before extensive lateral work will be started.

Ore shipments from this district for the week ending July 24 totalled 145 cars, an increase of 9 as compared with the previous week. The Chief Consolidated shipped 50 cars; Tintic Standard, 27; Victoria, 9; Eagle & Blue Bell, 8; Iron Blossom, 8; Dragon, 8; Grand Central, 6; Iron King, 6; Centennial-Eureka, 5; Mammoth, 4; Bullion Beck, 4; Gemini, 3; Tintic Drain Tunnel, 2; Gold Chain, 2; Colorado, 1; Swansea, 1; Ridge & Valley, 1.

BRITISH COLUMBIA

INTERNATIONAL CONVENTION AT NELSON.

HEDLEY.—There now are employed at the Nickel Plate mine about 150 men, two-thirds of whom are at work underground and the remainder at the mill and power-plant. The company is extracting gold-bearing ore averaging \$9 per ton. As it costs about \$8.50 per ton to mine and mill, the profits are not large. Development is planned in the expectation that richer ore will be found. Ore-cars holding two tons run on a narrow-gauge electric railway for a mile out of the mine. Then the ore is dumped into a tippie at the top of a steep side-hill. From the tippie it is dumped into cars operating on long steel cables and running down a side-hill that seems almost perpendicular. The long slide to the mill in the town itself is made in two sections and passengers who go up or down on the ore-trams sit tight and pray that

nothing breaks. A trip to the 'Nickel Plate' in one of the little ore-cars beats any roller coaster.

VICTORIA.—That oil has been discovered in commercial quantities in the Peace River country is reported. Crude oil, it is said, will be delivered to customers before the end of the present season. In No. 1 well the bore is being enlarged from six to eight inches; this work has progressed beyond the 1000-ft. point. No. 2 well, $2\frac{1}{2}$ miles below Tar island, has been started. Equipment is being installed at Hudson's Hope, and on the upper and lower Smoky river. At the San Joaquin well it is said that 20,000,000 cu. ft. of gas is escaping daily, that it is a wet gas containing a good deal of gasoline, and that the well will be capped and provision made for the recovery of the gasoline and the saving of the gas. The Department of Mines, Ottawa, claims to have discovered a process by which crude oil may be recovered from the tar sands which occur so extensively in the neighborhood

present time it was being worked nearly at full capacity. This produced more zinc than Canada required, but markets had been secured in Great Britain and Japan. The company has made a long-term agreement to treat the concentrate produced by the Canada Copper Corporation, and for this reason the copper plant had been increased from a capacity of 20 to 50 tons per day. Ground has been broken for the Rossland-ores concentrator, and the plant will be finished some time next year. The water for this plant has been provided by a large pumping-station situated a mile above the smelter on the Columbia river. The pumping-plant has a capacity of 3,500,000 gal. per day. An interesting exhibit at the convention was some samples of heavy crude oil that had been collected from seepages in the extreme south-western part of British Columbia.

ARMSTRONG.—J. Hamil has located a 6-ft. vein about a mile from the head of the Okanogan lake, and has

THE KIRKLAND LAKE MINE, ONTARIO

of Athabasca river, near Fort McMurray. A reserve of 55,000 acres of such land has been created.

NELSON.—From the start the third International Mining Convention, held July 20 to 24, went with a swing, and Fred A. Starkey, secretary, and his colleagues in the management are to be congratulated. There were several good addresses and a number of interesting papers that were productive of lively discussion. The side-trips to mining and metallurgical plants were enjoyed thoroughly, and every visitor came away from Nelson feeling that he had had a really instructive as well as agreeable time. The invitation to the convention finished with: "There's a Kick in every Smile—at Nelson. There's Dew in the Mountains Still", and there was. Among the speakers were Nichol Thompson of Vancouver, Glenville A. Collins of Seattle, S. S. Fowler of the Canadian Metal Co., A. G. Langley, and William Sloan, Minister of Mines. T. W. Bingay, comptroller to the Consolidated M. & S. Co., in the unavoidable absence of J. J. Warren and G. S. Blaylock, gave an interesting account of the company's doings and plans. He stated that the electrolytic-zinc plant had a capacity of 75 tons per day, and that at the

stripped it for 600 ft. An assay from the ore gave a return of 33 oz. per ton in silver and 21% lead. This claim was staked 28 years ago, but was allowed to lapse. Mr. Hamil was one of the original discoverers. The re-location has caused considerable local excitement, and several other claims recently have been staked in the neighborhood.

GREENWOOD.—Notwithstanding the departure of the B. C. Copper Co., now called the Canada Copper Corporation, from this neighborhood there is a great activity in mining and high-grade ore is being shipped. The Providence mine is the leader both in quantity and quality. Some remarkably rich ore has been taken from this mine recently.

VANCOUVER.—Charles F. Law, of this city, recently returned from England, where he succeeded in raising money for the development of placer claims at the mouth of Slate creek, on the Tulameen river, and on Keithley creek, near Little Snowshoe, Cariboo district. The shaft on the Tulameen river property will be continued to bed-rock, and drifts then will be run. Test-pits will be sunk and drifting done at the Keithley creek property. For

several years Robert Harrison has worked rich ground at Keithley creek by drifting and sluicing. His work last year is said to have given him a return of \$150 per day. Last fall he sold to a Philadelphia syndicate, retaining an interest in the management of the property. The Canadian Geological Survey has placed an excellent collection of Canadian minerals on display at its branch office, in Pacific building, for the benefit of prospectors. The B. C. Chamber of Mines is making a collection of minerals for display at the fall exposition in this city. Mine-owners and prospectors are asked to contribute.

ONTARIO

MINING ASSOCIATION OF ONTARIO RESENTS IMPLIED CHARGES.

COBALT.—Following the opening of the Gillies Limit, lying adjacent to the Cobalt silver area, quite a number of prospectors entered the field on July 20, and staked a large number of claims. No discoveries of importance have been reported, but the geological conditions peculiar to the area bear a marked resemblance to the producing territory. An average of from 125 to 150 tons of ore from the dumps of the Kerr Lake mine is being shipped to the Dominion Reduction plant, and from the early returns the indications appear to be that the 75,000 to 100,000 tons of dump material may prove to be a substantial source of revenue. The price of silver will have a vital bearing on the final result.

The Mining Corporation is constructing camps and making arrangements to carry on exploration work on a group of claims in Butt township, in the Nipissing district, where there have been discoveries of pitchblende containing an encouraging amount of radium. It is said that the radium-bearing material occurs only in patches and is of a grade that should make commercial operation feasible provided the patches are not too widely separated. On August 1 the Coniagas paid a dividend of 2½%, amounting to \$100,000 and making a total of \$400,000 paid so far this year. The mine has produced a total of over 28,000,000 oz. of silver to date, and is still producing at the rate of close to 900,000 oz. annually. Total dividends paid amount to \$10,040,000. Production from the McKinley-Darragh is averaging between 55,000 and 60,000 oz. of silver monthly. Net profits are adequate to meet current dividend disbursements of 3% quarterly. The treasury surplus is more than equal to a full year's dividend requirements. Production up to the end of June reached a total of 18,907,250 ounces.

Andrew B. Cullen, of Haileybury, owner of an instrument with which he claims to be able to locate metal deposits, has been engaged by a New York syndicate to go to the Cocos islands to locate treasures hidden by the pirates of old, notably Captain Kidd. Mining men have failed to recognize any merit in the instrument during the course of experiments conducted in Northern Ontario.

The Ontario Mining Association has requested the Ontario government to institute a search of records and conduct a complete investigation of the Department of Mines. The reason for the request is that Premier Drury

recently stated that the Government had found the Department of Lands and Forests to be "positively rotten", and that the Mines Department might be the next in line for investigation. Mining interests have resented the implied slander and are making a general demand to have the matter cleared up by the broadest possible investigation. They are confident that no irregularities will be found.

GOWGANDA.—A slab of silver ore from the Miller Lake-O'Brien mine has been shipped to the Royal Museum at Toronto. The ore is nearly one-quarter silver and the slab, which is 42 in. wide, is officially stated to contain 7000 oz. of silver per ton. It is undoubtedly the richest sample of silver ore produced by the Northern Ontario mines, since the early days of the Cobalt camp. Statements of new discoveries of a highly sensational character at the Miller Lake-O'Brien, which have recently obtained widespread circulation, are officially denied.

PORCUPINE.—The McIntyre, in diamond-drilling from the 1500-ft. level, has penetrated a vein of good ore at about the 1600-ft. level, the deepest point at which gold has been found in the mine. At the Dome Mines a spectacular discovery is reported at the 850-ft. level, but the statement lacks confirmation. It is known, however, that the orebody at that depth is 43½ ft. wide and has an average gold content of \$7.60 per ton. Until two years ago the estimate of ore-reserves averaged only \$5.10 per ton, and the increase of 50% in this value at the depth reached is regarded as of great importance. It is understood that the question of exercising the option held by the company on the Dome Extension will be dealt with at a meeting to be held in August.

There is strong probability that the directors of the Porcupine Vipond-North Thompson will accept the offer of a Toronto syndicate to underwrite 600,000 shares of treasury stock at about 30c. per share. This plan would provide funds to enlarge the mill so as to treat 150 tons daily at a cost of \$50,000, as well as greatly increase the scope of underground operations.

The shaft on the Keora is down 190 ft. When a depth of 250 ft. is reached lateral work will be undertaken to cut veins No. 5 and 6, encountered in diamond-drilling which showed high gold content.

KIRKLAND LAKE.—The Lake Shore during June treated 1535 tons of ore with a recovery of \$37,546, being an average of \$24.46 per ton. Production showed a falling off as compared with May, owing to a shortage of electric power. The output for the first six months of the current year aggregated \$244,710. Arrangements for starting work on the Tough-Oakes have nearly been completed, a few details in connection with the taking over of the mine by the Kirkland Lake Proprietary remaining to be settled. The staff has been engaged and the mill increased in capacity by the addition of another ball-mill and other equipment. There is ore on hand sufficient to keep the mill in operation for eight months. The Burnside, which is also embraced in the merger with the Kirkland Lake Proprietary, is expected to prove an important source of ore.

THE MINING SUMMARY

OUTPUT OF THE COPPER MINES

Comparative figures of copper production for the first half of the current year reflect the condition of the market. In the first two months of this year about 300,000,000 lb. of copper was sold. This, with the 450,000,000 lb. disposed of in November and December of last year, brought total sales on that movement up to 750,000,000 lb. Since then it has been a buyers' market. While the amount of metal contracted for in that period would ordinarily cause a slight cessation in buying for a month or two, reappearance of some demand should have been made before this. Faced with such lethargic metal-market, producers are generally sticking to the curtailment schedules determined upon early last year. Anaconda is showing a slight expansion in production. Prior to April the company was producing about 18,000,000 lb. of smelter copper per month against 13,000,000 monthly a year ago. In the first six months it produced 93,250,000, or over 13,000,000 lb. more than in the same period 1919. Phelps Dodge and Utah, on the other hand, are 8,000,000 and 11,000,000 lb., respectively, behind last year.

Total production of twenty representative mines amounted to 648,023,716 lb. of blister copper in the period ending June 30 last; in the corresponding period last year these mines produced 580,098,152 lb., or about 68,000,000 lb. less. The South American mines are all ahead of 1919, Chile showing a gain of 20,000,000 lb. With its Latin subsidiary, Braden, Kennecott is up 22,000,000 lb. from its 1919 production pace. Output of these properties is shown below.

	June 1920 Lb.	May 1920 Lb.	January to June 1920 Lb.	January to June 1919 Lb.
Anaconda	12,700,000	9,700,000	93,250,000	79,950,000
Phelps Dodge	7,552,000	7,902,000	46,730,000	54,431,144
Utah	10,000,000	9,904,781	46,017,999	57,276,000
Kennecott	10,120,000	9,311,000	53,653,860	31,554,000
Calumet & Hecla	9,032,879	8,803,811	55,490,266	52,465,514
Chile	10,000,000	10,300,000	53,866,000	30,860,000
Inspiration	7,300,000	7,500,000	41,700,000	39,200,000
Chino	4,010,069	3,930,728	22,156,025	22,261,277
Miami	4,400,000	5,034,760	27,931,482	28,152,031
Ray Con.	4,520,000	4,200,000	24,964,073	23,927,000
Nevada Con.	4,650,000	4,350,000	24,871,938	23,378,482
Calumet & Arizona	3,812,000	3,840,000	21,180,000	22,188,000

Old Dominion	2,999,000	2,287,400	14,432,700	14,714,000
East Butte	1,396,140	1,412,760	8,908,820	8,900,840
Granby	2,079,000	2,131,219	12,566,558	11,407,563
Greene-Canaanee	3,750,000	4,300,000	22,150,000	18,200,000
Cerro de Pasco	3,944,000	6,890,000	29,668,000	28,096,000
North Butte	1,616,822	892,118	9,153,995	5,940,301
Total	110,535,910	109,490,577	648,023,716	580,098,152

*E-estimated.

COURSE IN MINERALOGY

The Technical Department of the Extension Division, University of California, announces a new course by correspondence in determinative mineralogy and blowpipe-analysis by Arthur S. Eakle, professor of mineralogy. It is equivalent to the course given in the regular session of the University. Two units of university credit will be given, if desired, on the passage of an examination. Each of the ten assignments are based on portions of a textbook which is sent out with the preliminary announcement sheets. The

fee for this course is \$12, payable in advance. This will include all assignment sheets, the text-book, all powders and mineral specimens, a pad of report blanks, postage on all material sent to the student, and the supervisory work of the instructor over each student. Necessary apparatus for the course must be provided and will be furnished by the Associated Student's Store, Berkeley, California, on receipt of a check or money-order for \$20. The difference between this amount and the actual cost will be returned. For those who have access to a laboratory or who already have blowpipe apparatus the charge can be reduced to a few dollars only. A list of the necessary laboratory equipment will be sent on application.

CALIFORNIA

Amador County.—The 1500-ft. Gover shaft of the Fremont Consolidated has been cleared of water and the pumps are now engaged in unwatering the main Fremont shaft, which is approximately 3000 ft. deep. Immediately following clearance of the lower levels repairs to the shaft will be rushed and prospecting and mining resumed. The Fremont shaft will be sent deeper and effort made to determine extensions of orebodies which formerly yielded high-grade ore. The property is being re-opened under an option by a strong company after lying idle two years.

New pumps have been added to the plant at the Argonaut mine and unwatering is proceeding more rapidly. Freezing of sections of the pumps, attributed to the use of compressed air, has caused some trouble. Repairs are following unwatering and the management is endeavoring to have the property in shape for production as soon as the water is out of the lower levels. The disastrous fire, which forced flooding of the property, is definitely extinguished, and before the end of the year the Argonaut should again take its place among the gold producers of the State.—Labor shortage is hampering work at many local mines, and at the Central Eureka the management has been forced to curtail operations to such an extent that only 20 stamps are dropping. It is presumed that with the passing of the harvest and lumbering season labor for the mines will become more plentiful.

Placerville.—The 700-ft. tunnel of the Pacific Channel Co. has entered the long-sought channel and is advancing to reach a deposit of cemented gravel. Indications point to the proximity of a large body of gold-bearing material. The property lies about 16 miles east of Placerville.

A number of small quartz and placer mines in territory tributary to Placerville are receiving attention, despite a scarcity of skilled labor and the adverse circumstances affecting gold mining. Some promising discoveries have been reported and several companies are preparing to resume placer mining as soon as the rainy season provides sufficient water.

Plumas County.—At a point 1500 ft. north of the Walker property Frank Morehouse has penetrated a 16-ft. vein of good ore at a depth of 510 ft. This development, while generally predicted by those who were familiar with the country, gives promise of another producer.—Arizona parties have taken a bond on the Five Bears mine, and will

soon commence extensive work there.—Spokane capitalists have taken a bond on the Eagle group and plan development on that property and San Francisco interests expect to commence work on the Trimetallic group adjoining the Engel mine.—Work on the Beardsley copper mine and mill is going ahead satisfactorily. Tunnel No. 3 is rapidly nearing completion. This will facilitate handling the ore from the mine to the mill. Some mill machinery is installed and more is on the way. The owners are planning to enlarge the capacity of the mill, as recent work has demonstrated that the orebodies are greater than was estimated.

Redding.—The Bully Hill Mines Co. has purchased the Balaklala Copper Co.'s smelter buildings at Coram to get structural steel for erecting reduction works and other buildings at Bully Hill. None of the machinery at the Balaklala smelter was purchased. It is estimated there will be 200 carloads of steel to be shipped by rail to Bully Hill, where workmen already are grading for the new buildings.

COLORADO

Denver.—The management of the Lackawanna Oil Shale Products Co. announces that the first unit of its plant near DeBeque is almost completed. The first unit, it is stated, will handle 250 tons of shale per day. It is the intention to increase the size of the plant to 1000-ton capacity. A pipe-line is now being laid from the plant to DeBeque, a distance of $7\frac{1}{2}$ miles, from which point the company expects to ship its finished product. John Gaffy, president of the company, has spent several months in studying various processes for the extraction of oil from shale and it has been decided to use the Randall method, which is reported to be far simpler in mechanical operation than many of the other methods. The Randall process, it is stated, is a modification of the inventions of J. W. H. Randall, which were used with reported good success during the War by the American and Allied governments in the manufacture of wood alcohol and acetone, from waste wood products, both substances being used in the manufacture of munitions.

IDAHO

Coeur d'Alene.—The Russell shaft, being sunk by the Federal company to prove its contention in the apex litigation with the Hecla company—that the apex of the east orebody is within the Russell claim, owned by the Federal and under lease to the Marsh—is now down 240 ft. The Federal company has placed a new hoist in position, since taking over the shaft, that is capable of handling the work to the depth of 1000 ft., and has practically re-timbered the shaft and otherwise placed it in a safe and workable condition.

NEVADA

Manhattan.—The annual report of Charles Kirchen, consulting engineer to the Consolidated Spanish Belt, operating near here, estimates the "probable ore" in the mine at 25,000 tons worth \$20, and 50,000 tons worth \$30. The engineer says work now being done may open another 100,000 tons; 6000 ft. of development work has been done, according to the report. It is expected to have a 50-ton concentrator in operation before the end of August.

Rochester.—One foot of ore assaying \$350 per ton in silver, lead, and copper has been opened in the bottom of a 190-ft. winze in the Mayer-Preston lease on the Buck & Charley. The full width of the winze assays \$60 and shipments of this grade of ore have been started. Several months ago shipments from drifts at the bottom of this winze reached 300 tons monthly, some of the ore assaying more than \$500 per ton for a width of two feet. The ore recently opened was found when sinking of the winze was resumed.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

A. T. Watson is in Peru.

Augustus Locke is in Utah.

D. C. Jackling is at Salt Lake City.

John B. Hastings is at McGill, Nevada.

Nicolas G. Berger, from Bodaibo, Siberia, is here.

Frank C. Loring has returned from London to Toronto.

John W. Mercer, of New York, is at the Fairmont hotel.

E. M. Hamilton has returned from London to San Francisco.

John P. Gray, mining attorney of Coeur d'Alene, Idaho, is in San Francisco.

H. W. Hardinge left for London and the Continent on the 'Aquitania' on July 31.

Percy R. Middleton, on his return from New York, has gone to southern Arizona.

Emmet D. Boyle, mining engineer and Governor of Nevada, is at the Palace hotel.

A. H. Richards has been appointed general superintendent of the Garfield smelter, in Utah.

Ben. B. Thayer, vice-president of the Anaconda Copper Mining Co., is at the Palace hotel.

L. J. Mayreis has renewed his engagement with the Burma Corporation as resident manager in India.

Arthur F. Taggart, of New Haven, now professor in Columbia University, was in San Francisco this week.

F. H. Skeels has been appointed superintendent of the Ramshorn mine of the Ramshorn Mines Co., at Bayhorse, Idaho.

Oscar Osolin, electrical and mechanical engineer for the Lenskole Gold Mining Co., of Bodaibo, Siberia, is in San Francisco.

R. F. McElvenney, plant manager of the Garfield smelter, has been appointed manager of the A. S. & R. Co.'s lead refinery at Omaha.

Sumner S. Smith has resigned as Mine Inspector for Alaska to take charge of coal mining for the Navy under the Alaskan Engineering Commission.

Robert N. Bell, State Mine Inspector of Idaho, will resign at the end of the year, after 16 years of service, to take up the private practice of engineering at Boise.

Frederick B. Tough, of Colorado, petroleum technologist of the Bureau of Mines, has been appointed supervisor of oil and gas drilling operations under the leasing law.

B. A. Middlemiss, assistant general manager for the Chile Copper Co., is making a visit to the principal mining centres of the United States. He was at Salt Lake City recently.

L. Everett, manager of the McKnight Mining Co.'s mines at Mokelumne Hill, California, is on his way to Colombia, South America, to investigate oil and platinum properties.

Donald D. Riddle and Roger F. White have been appointed valuation engineers in the oil and gas section, Income Tax Unit of the Internal Revenue Bureau. Paul Ruedemann has resigned.

H. L. Norton, formerly general superintendent for the Arizona Commercial Mining Co., has been transferred to the office of the general manager for the Phelps Dodge Corporation, at Douglas.

THE METAL MARKET

METAL PRICES

San Francisco, August 3

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	19.25
Lead, pig, cents per pound.....	8.75-9.75
Platinum, pure, per ounce.....	\$105
Platinum, 10% iridium, per ounce.....	\$155
Quicksilver, per flask of 75 lb.....	\$88
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

August 2.—Copper is inactive but firm. Lead is quiet but very strong. Zinc is dull but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

AMERICAN SMELTING & REFINING CO.

The American Smelting & Refining Co. earned the \$2 semi-annual dividend on the common stock by a comfortable margin in the six months ended June 30, 1920, a decided contrast to the corresponding period last year when only 4c. per share was earned and a deficit of \$1,195,464 was left after payment of the common dividend. In the first six months of 1919 the net increased to \$2.12 per share, and progressive improvement has since been shown, largely due to more favorable conditions in Mexico and better demand for copper.

In the first six months of this year the company made big inroads into its copper accumulation and was able to dispose of 40 to 50% of the metal it was carrying for other companies. How the cash position has been strengthened may be gleaned from the fact that working capital, including metal stocks, stood at \$57,680,916 at the close of 1919, against \$57,988,518 at the close of 1918, whereas, excluding metal stocks, it fell to \$8,919,808 as of December 31, 1919, against \$13,946,422 at the end of 1918. Operations of Mexican mines are now approximately 90% of normal. Rapid strides are being made toward completing the unwatering of properties which became flooded during years of diense, and capacity ore production is expected before the close of the year. The company's five Mexican smelters are now running full blast. With promise of stable government below the Rio Grande, officials hope for a restoration of normal conditions in Mexico, under which they were able to show net income of \$6 per share from Mexican properties alone in former years.

INTERNATIONAL NICKEL CO.

Sentiment among people conversant with affairs of the International Nickel Co. has taken a decided turn for the better. The company is said to have definitely rounded the corner and its business is considerably better than for some time. This condition may be expected to be reflected to some extent in the report for the three months ended with June. While surplus stocks of nickel held abroad and difficulties of transportation in this country materially reduced demand in the fiscal year ended March 31, officials are encouraged by better business since that time. It may be presumed that plant operations are at a higher rate than the 60% capacity averaged during the three months ended March 31; that 60% capacity represented 80% of former capacity, as the Port Colborne plant was included in the percentage for the March quarter.

Not a little of the improvement is the result of new markets the company is constantly developing for its monel metal, an alloy made up of the same component parts as are found in nickel ore. One of the uses for monel metal is in the construction of racing yachts. A large amount was used in the construction of the 'Resolute', as well as in the 'Vanitie'. Another wide use is in golf clubs, where non-rusting qualities are important. The nickel company's financial position was greatly strengthened in the last fiscal year, and at March 31 it had a working capital of nearly \$9,500,000, against \$9,779,045 on March 31, 1918. The working capital on March 31 last was larger than at any time during the previous three years. Possibility of resuming dividends on the common stock is believed to be somewhat remote, although the company is in a strictly liquid position, with earnings showing real improvement.

MONEY AND EXCHANGE

Foreign quotations on August 3 are as follows:

Sterling, dollars:	Cable	3.70 1/2
	Demand	3.71 3/8
Francs, cents:	Cable	7.69
	Demand	7.70
Lire, cents:		5.37
Marks, cents:		2.31

Eastern Metal Market

New York, July 28.

Mid-summer dullness pervades all the markets, but prices in most of them are firm. There is a marked disappearance of speculation in copper, lead, and zinc.

Demand for copper continues of moderate proportions and prices are firm.

The tin market is quiet; small transactions are confined to dealers.

Pronounced strength characterizes the lead market and prices have advanced.

There is but little life to the zinc market and prices have eased slightly.

Antimony has declined somewhat.

IRON AND STEEL

Steel works in the Pittsburgh district will soon be forced to a further lessening of output because of the railroad situation unless unexpected relief is soon afforded. Developments at Chicago have been unfavorable because of the strike of the coal miners of the State. Five more blast-furnaces have been banked there, so that the Steel Corporation has only 14 in blast out of a total of 29 in that district.

Steel producers from Pittsburgh and Youngstown have gone to Washington to obtain relief, because they state that the threatened coal famine in the North-West and the grain movement in the West are diverting an excessive number of cars.

Generally speaking, new inquiry on finished products has decreased. Reports from the automobile trade are conflicting. Indications are that there is a letting-up because of the smaller operations by manufacturers of axles, springs, and other parts. Demand for trucks has fallen off, because the financial situation is causing users to cease buying or to cancel orders.

COPPER

Business from both domestic and foreign consumers continues of moderate proportions. Prices are firm at 19c., New York, for both Lake and electrolytic copper from the large producers. From small producers and particularly from dealers the supply is light and only small quantities are available around 18.75c., New York, for early delivery. Leading interests are selling for August-September delivery at 19c. and some are asking 19.25c. for delivery in the last quarter. An encouraging sign is that demand from consumers for shipment on contract is better and also that shipments from refineries are easier. The June production of smelters was about 115,000,000 lb. by 20 representative operators, which made about 650,000,000 lb. in the first half. Copper exports thus far this year have been only a little less than the rate which was a record in 1913.

TIN

Conditions are but slightly changed and the market continues quiet. There is no demand from consumers who have been out of the market now for some weeks. It is even said that one large consumer was offering October shipment metal, but this is not confirmed. Last Thursday low prices were quoted for future shipment at 48.25c. The spot Straits market is nominal with the quotation yesterday at 48.50c., New York. Metal for this position continues hard to obtain. In the week, sales on the New York Metal Exchange have been small, one of 25 tons of July-shipment Straits going at 48c. last Thursday and 25 tons of August-September on Monday at 49c. The London market is quiet with spot Straits quoted at £282 per ton yesterday against

£288 a week ago. For spot standard tin the quotation was £267 and for future standard it was £271. Arrivals thus far this month have been 3385 tons, of which 720 tons is credited to Pacific ports. The quantity afloat is 4715 tons.

LEAD

The American Smelting & Refining Co. last Wednesday, July 21, advanced its price 3c. per pound to 8c., St. Louis, or 8.50c., New York, thus recognizing the strength of the market, which continues to expand. But this price is still considerably below the outside market, which yesterday was quoted at 8.75c., St. Louis, or 9c., New York, at which level sales have been made. This situation is due to continued good demand in spite of high prices and to limited output, which is stated to be about 60% of normal. Prompt-shipment lead from the West has sold at 9c., New York, at which level it is scarce. It is believed that August lead cannot be had at less than 9c., New York, and perhaps September lead, also, at no better price. There is no question but that import lead will soon appear in this market, as it is reported already on the way.

ZINC

Conditions in this market do not improve greatly and business is of the hand-to-mouth order and light at that. Galvanizers and brass-makers are buying only as they need it, due either to light business or large stocks. Producers are unwilling to sell beyond September, so uncertain are they of the future. Ore is high and present zinc prices do not net much profit. What the situation as regards labor and ore will be in the fall, no one can tell, and hence the conservatism. Prime Western for July, August, and September delivery is quoted at 7.85c., St. Louis, or 8.20c., New York.

ANTIMONY

Heavy stocks and offers of shipment at prices about equal to the ruling spot price have caused an easier tendency. Wholesale lots for early delivery are quoted at \$7.25, New York, duty paid.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, are quoted at 33c., New York, by the leading interest and at 31.50c. by other sellers, both for early delivery.

ORES

Tungsten: The general situation is unchanged. Demand is light and prices are nominally unchanged at \$6 and upward per unit, depending on the grade and the delivery.

Ferro-tungsten is quoted at 80c. to \$1.10 per pound of contained tungsten.

Molybdenum: Quotations are nominal at 65c. to 75c. per pound of MoS₂ in regular concentrate and the market is devoid of features.

Manganese: There have been offerings of Indian ore at 75c. per unit, but no sales, as most users are unwilling to pay more than 70 cents.

Manganese-Iron Alloys: The ferro-manganese market is quiet with inquiries light and sales confined to small lots for early delivery. Quotations are unchanged at \$225 per ton, delivered, for early delivery and \$200 for forward delivery. The spiegeleisen market is strong and unchanged at \$75, furnace, with one inquiry for 600 tons before sellers.

The production of silver in Mexico has averaged in recent months about 6,500,000 ounces.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

LIGHTING DRAFTING-ROOMS BY ELECTRICITY

Modern methods of lighting drafting-rooms are discussed in Bulletin L. D. 108, recently issued by the Edison Lamp Works of the General Electric Company.

There are now three methods generally accepted of supplying light, known as direct, semi-indirect, and totally indirect. With direct lighting a reflector is placed above the lamp, or an enclosing globe around it, sending the larger part of the light at once to the desk level. A semi-indirect unit consists of a translucent dish, bowl, or reflector placed below the lamp, sending most of the light to the ceiling, from which it is reflected downward, but allowing part of the light to be diffused through the glass. A totally indirect unit consists of an opaque reflector below the lamp, sending all of the light to the ceiling.

Direct lighting with efficient reflectors is unquestionably the most economical, as far as current consumption is concerned, of the three methods, for with it the color of walls and ceilings have less effect on the resultant illumination. Direct lighting, if improperly arranged, may produce glare either from the light sources themselves or by reflection from the objects lighted, or it may distribute the light unevenly and as a result produce dense shadows. Nevertheless, thousands of satisfactory installations of good direct office-lighting are to be seen, employing translucent glassware rather than opaque reflectors, thus avoiding the undesirable condition of a dark ceiling and the gloomy appearance of the room. Many forms of semi-enclosing glassware of the direct type are giving very satisfactory service.

Totally indirect lighting is probably the most 'fool-proof' from the standpoint of a glaring installation. The light is usually evenly distributed and comfortable. Objections have been raised that there is a total absence of shadow, making the room appear flat. If the system is properly designed, however, this is not true.

Semi-indirect lighting is an intermediate practice; it is more efficient than totally indirect and much better for the eye than the average direct-lighting system. Semi-indirect lighting is not glaring if the proper unit is chosen; the light is quite evenly distributed and such shadows as are produced are very soft and do not become annoying. The fact that the place where the light originates is readily discernible, has a psychological effect on the average individual, and makes many people feel more at ease under semi-indirect lighting than under totally indirect.

A semi-indirect unit, first, should be of quite dense glass; in other words, transmit but a small portion of the light, if the best conditions for the eye are to be obtained. If light density glass is used, the bowl becomes very bright and the system loses many of its advantages, dropping back to the direct-lighting class where a number of fairly bright objects are in the field of vision. Second, the fixture or hanger used should be of such a length and the socket in the proper relative position to the bowl that the light is directed in such a manner as to illuminate the ceiling evenly. Many cases can be noted where the lamp is placed too low in the dish, concentrating the emitted light in a fairly narrow angle, resulting in a ring or circle of very bright illumination on the

ceiling directly above the unit with the spaces between units comparatively dark. At other times to get rid of this effect, the lamp is raised so high that from some parts of the room the filament becomes visible, introducing glare. On the introduction of the Mazda C lamp, with its rather concentrated filament, this feature became of more importance than formerly. Third, the glass used should be smooth inside and, preferably, outside, as roughed glass collects dirt very readily and is difficult to clean. Needless to say, all lighting fixtures should be regularly and carefully cleaned to keep the illuminating-efficiency at a maximum.

Although the lighting requirements of the drafting-room are somewhat exacting, they may be readily met if due care be taken in the selection and placing of lighting units. The ideal condition is an even distribution of well-diffused light of a high intensity. Shadows must be minimized, as they make it difficult to follow the fine lines when working close to the T-square or triangle. A high intensity of illumination is necessary. Five foot-candles is the minimum and should be supplied only for rough work. For the most exacting work, such as tracing from blue-prints, from 10 to 20 foot-candles will be required.

Semi-indirect systems where dense glass is employed, or totally indirect systems are probably the best suited, using from 1.5 to 3.5 watts per square foot. Direct general illumination of a high intensity using rather close-spaced semi-enclosing units is also used, where the ceilings are so dark as to preclude the use of indirect systems, and found satisfactory. The units should be located with reference to the drawing-tables and so arranged that the maximum light will come from the proper direction. Lamps must be hung well out of the angle of vision and every effort made to avoid glare. In both the direct and semi-indirect systems of illumination due note must be taken of the usual arrangement of boards relative to the windows, placing the lamps so that, as far as possible, the direction of predominant light is the same as that of daylight.

A system which is quite frequently found is the use of a diffused general illumination (1 to 2 foot-candles) supplemented by a local lamp for each drawing-board. This unit may be of several varieties, fixed or movable, attached to the wall or to the drawing-board, opaque or diffusing reflector, and various sizes of lamps; but in any case it is open to the usual objections of local lamps, namely, liability of glaring reflections, loss of time in shifting the lamps, and relatively high maintenance cost. Tracing may often be satisfactorily accomplished by having the top of the tracing table made of etched glass, and lamps with suitable reflectors placed below the glass, illuminating the work from beneath rather than from above.

NEW BOOKLET ON MODERN METHODS OF BELT-JOINING

Both the man who buys belting today and the man who has an investment in belting have a commodity which can only be replaced with delay, difficulty, and considerable expense, and the continuous performance of which is essential for maintenance of production schedules and operating at

minimum cost. One of the biggest problems the belt-user has to face is that of joining the belt in a way which preserves its strength and ensures its longest and most satisfactory service. Obviously, no belt can give better service than its joint will permit, and if destructive methods are employed which punch out valuable material or weaken the longwise power-carrying belt-fibres the service and the life of the belt are impaired. A new booklet entitled 'Modern Scientific Methods in Belt Joining' contains practical belt-joining data for the practical man. This information is of permanent value to anyone interested in the upkeep of belts and the book is so designed that when it is tacked to a wall it presents on one page full information for joining the belt to ensure its best service under all conditions of work. The instructions as to how to make belt joints which retain the belt's full strength and assure its longest life are given in simple and concise language and are amply illustrated. The larger illustrations show in full size the outside and pulley sides of Crescent joints. A cross-section illustration shows how a belt can be joined without weakening it in any way, and is a vivid demonstration of how the Crescent method retains the full strength of the belt and actually reinforces it. It also shows how the Crescent method prevents metal coming in contact with the pulley and thereby eliminates noise, wear, and crystallization. Copies of this illustrated circular, form N. Y. 227, will be sent upon request by the Crescent Belt Fastener Co., 381 Fourth avenue, New York.

NEW TYPE OF SHIP COMPLETED BY BETHLEHEM STEEL CORPORATION

The diesel-driven ore-steamer 'Cubore' has completed successfully her trial trip and will start on her first voyage to Cuba this week. The 'Cubore' is propelled by a Bethlehem two-cycle diesel oil-engine of 3200 hp., designed by Arthur West, one of the foremost gas-engine engineers in the United States and the designer of the largest and most successful gas-engine in the world. This ship represents the greatest single advance in marine engineering in fifteen years. Its heavy-oil engine, designed by an American, built by Americans, for use in an American ship, represents this country's first successful attempt in a field that has been held exclusively by foreign interests. The 'Cubore' will be used in carrying ore from the Bethlehem Steel Corporation's Cuban properties to the Bethlehem plants in the United States. The following are special features of the vessel:

Length overall, 469 ft.; length between perpendiculars, 450 ft.; breadth, molded, 57 ft.; depth, molded, to upper deck, 37 ft.; dead weight, about 11,500 tons; number of screws, one; revolutions, 105 per min.; type of boiler, Scotch; number of boilers, one; steam pressure, 140 lb.; heating surface, 1800 square feet.

REINFORCED-CONCRETE HIGHWAYS

A recent leaflet from the American Steel & Wire Co. says: "Steel and concrete have about the same ratio of expansion hence readily become as one integral mass. The great strength of steel is therefore imparted to every inch of the concrete in above manner. A concrete tower, or building, or sidewalk, or bridge, or ship, is invariably reinforced with steel fabric. A concrete highway has to stand more than either in that in addition to rending impact of heavy traffic it has to endure the tremendous heaving force of frosts that lift up the sides of the road as the first freezing occurs in the fall, lowering with the spring thaw, thus causing the long sprawling cracks lengthwise, mainly, of the road. But these cracks do not harm the concrete if bound together with steel as shown above, while the reinforcement greatly lessens the liability of the cracking.

"It is possible to reinforce concrete so strongly as to avoid any possibility of cracking, but the cost of such construction

makes it necessary to limit the steel to a certain adequate medium to fit the money available; and for the same reason the thickness of the concrete must be limited. But the concrete and the steel must go together—not one without the other. The steel must be evenly distributed throughout a concrete road to reinforce not only in one direction but in all possible directions to meet the crushing and abrasive forces of sudden and heavy loads imposed by a necessarily ever-increasing heavy traffic, and also the frost-stresses above described and the effects of washouts.

"For these reasons a concrete highway distinctly has a greater burden to bear than the tower, the building, sidewalk, bridge, or ship and hence a more urgent need of being adequately reinforced with steel. These points are, of course, admitted. It is simply a question of the amount of money available for the work. It prompts this suggestion—how much will it cost to make a mistake and have to build all over again?"

THE DINGS MAGNETIC SEPARATOR FOR WET CONCENTRATION

The Dings magnetic separator, type "BW", has recently been developed for concentrating wet ore. It is built upon a combination of the Wetherill and Dings principles. The pulp is fed upon a vanner belt which conveys it under the two magnetic poles. The magnetic material attracted to the poles is removed by the two cross-belts, and the non-mag-

Dings Magnetic Separator

netic material is discharged over the drive-pulley into the launder beneath.

The standard Wetherill machine has coils both above and below the belt. The lower coil would be water-soaked in a short time if used on a wet machine. A Dings bridge bar has been substituted for the lower Wetherill coil, completing magnetic circuit. The cross-belts, which remove the magnetic material, must be placed above the surface of the pulp; consequently a very large magnetic gap is required. The inverse law of magnetism and the wide gap necessitate a high-intensity field to attract the magnetic particles of ore in the pulp. There is a distinct agitating action caused by the magnetic flux in the pulp underneath the poles. This zone of agitation is of assistance in thoroughly washing and cleaning the magnetic particles and freeing them from any attached non-magnetic material. It also permits the machine to run faster than a standard dry machine for the same separation, and has for that reason a higher capacity.

One of the difficulties in dry magnetic separation has been the clinging of fine particles to the belt, and material finer than 100 mesh was difficult to separate cleanly. This wet-type machine is making a high-grade zinc concentrate from

ore ground so that 60% passes a 200-mesh screen. The consistence of the pulp is about one of solid to four of water. It has a capacity of 100 tons per 24 hours on a 48-in. belt. One of the main objections to magnetic separation is the dust and dirt from handling dry material as well as the cost of drying. This machine removes this objection and can be used with other wet-concentrating machines.

The coils of this machine are thoroughly impregnated by vacuum and pressure, and then encased, making them water-proof. The current can be varied by a large rheostat, and the poles may be raised or lowered independently to give any width of gap desired. The power required to drive and to energize the coils is small. The machine is sold outright, there being no royalty. It is made in five sizes with belt widths from 18 to 60 inches.

THE TRAYLOR SUPERPUMP

A recent development in pump manufacture is the super-pump made by the Traylor Engineering & Manufacturing Co.

That the power-driven pump is the most efficient and most economical machine for the handling of liquids is an incontestable fact. This is true for the reason that the stroke is a fixed and known quantity thereby yielding a measured displacement for each revolution. A further reason is that a much higher piston speed may be had with a crank-pump than with a direct-acting steam-pump. It is, however, no simple matter to build an efficient power-pump, due to the fact that problems are presented which are not found in the design of a direct-acting steam-pump. The chief of these are:

First: The piston speed of a plunger-pump varies throughout the stroke, inasmuch as the crank describes a circle while the plunger moves in a straight line. It will thus be seen that the velocity of the plunger increases from zero to maximum and then decreases from maximum to zero.

Second: Water is practically incompressible and therefore the velocity of the discharge is at all times in direct proportion to the speed of the plunger.

Consideration of these points will show that the pump-chambers and the pipe-line are subject to shocks or pulsations depending in severity upon the speed and pressure. This does not occur in steam-pumps. As a consequence, simplex and duplex power-pumps have little advantage over direct-acting steam-pumps, notwithstanding the wastefulness and low efficiency of the latter. It is clear, then, that the solution lies in the multiplication of plungers, and when three or five are used, the power-pump rises superior in efficiency and economy. The reason is, of course, that the cranks being set equal distances apart (120° in the triplex or three plunger, and 72° in the quintuplex or five plunger), the pulsations overlap, so that the discharge from the pump-chambers is nearly uniform in quantity and pressure.

The Superpump is a machine of simple and sturdy ruggedness. The design is heavy, the use of metal lavish—to minimize vibration and forestall fracture. The water passages are large and free from angles; valves are ample in area and bearing pressures are low. The pump is simple to operate and easy to maintain and the delivery is steady and reliable. An especially valuable characteristic of the Superpump is its very economical use of power; it pays its way easily and leaves a margin for substantial profits.

All these advantages combine to make the Superpump the most efficient, economical, and dependable pump purchasable. In a pump, initial cost is negligible when operating and upkeep expenses are held down to the minimum and here is where the Superpump excels.

The Superpump is a vertical, single-acting, outside-packed plunger-pump—the pattern which all engineers agree is the

most compact, durable, and efficient. The design offers the following advantages:

1. It is the only pump which will successfully handle gritty or acid water.
2. Leakage is noticed as soon as it occurs and packing can be adjusted without stopping the machine.
3. Lubrication of any part can be accomplished during operation.
4. The pump is single-acting, so that all the working thrust is always in one direction, minimizing wear and vibration.
5. All strains are taken on finished bolts, eliminating loose joints and consequent packing.
6. The machine is highly sectionalized, which cuts down repair bills. As every part is easily accessible, only the single inexpensive part directly affected need be removed. Also, by this construction, pumps of large size may be taken to, and erected in, places that would otherwise be inaccessible.

Some details of the construction of the pumps, two types

Type D, Quintuplex Superpump. Drive 102

Type DD, Quintuplex Superpump. Drive 100

of which are shown in the accompanying illustrations, are of special interest.

The crankshaft is the single piece, which is conceded by all users to be superior to the composite or built-up type, by reason of its greater resistance to deflection. Our crankshafts are made of the highest grade open-hearth steel, cast on end, and designed for a strength of sixteen to twenty times the plunger load. The connecting-rods are the adjusting type with forged steel strap, cast-steel stub and bronze bearings, correctly grooved for proper lubrication. A wedge and screw is provided on the crank end, by means of which micrometer adjustment may be had. On rods with crank-pins five inches and less the wedge is under the bearing while on larger sizes it is on top. A cradle of semi-steel is securely bolted between the standards and is bored out for the crossheads or for crosshead-ways. Usually the cradle is fitted with ways or guides for the crossheads to work in. The ways are generally made of cast-iron, but in special cases may be of bronze. They are turned to fit the cradles and bored for the crossheads.

The crossheads are made of hard close-grained cast-iron

carefully turned and polished to fit the ways. They are made of such size that the pressure on the ways does not exceed 45 lb. per square inch. In some cases, the cross-heads are fitted with adjustable shoes, the cradle being then merely bored out for the crossheads. Such shoes may be of cast-iron or bronze and are adjusted by means of setscrews. Adjustment is on an inclined plane, thus keeping the cross-head-pins in the centre of the guides and securing even distribution of the load.

Each working barrel is a separate casting, either bolted between standards or to adjacent barrels. Liberal flanges are provided for attachment of valve-chambers. In some cases the working barrel and valve-chambers are made in one casting. The working barrel is made of cylindrical shape, which is the strongest form. For pressures to and including 750 lb. working barrels are made of semi-steel; between 750 lb. and 2000 lb. open-hearth cast-steel is employed, while above 2000 lb. they are of forged steel, worked out of the solid. Attachment of barrels to each other or to the standards is by means of turned bolts. The stuffing-boxes are of extra depth to minimize friction and prevent leakage. High-grade waterproof packing, suitable for the service demanded in each instance, is provided. The packing is adjusted by glands, made of semi-steel, or cast-steel, as required. They are held in position by hinge-bolts or studs, according to the construction of the pump. The plungers are made of hard close-grained cast-iron, chilled iron, or forged steel as the service demands. All plungers are machined and ground to exact size and perfect finish. Plungers are securely attached to the crossheads and can be easily removed. The valves are the most important part of the pump and they are therefore accorded particular attention. The valves in every Superpump are specially designed for the particular service contemplated and may be single or multiple, of the disc type with grid or annular seats, or, in the case of heavy liquids or those carrying solid particles, of the ball type. In the disc type, the seats, plates, and stems are made of bronze of high tensile strength and phosphor-bronze springs are used. The disc-valves have renewable faces of fibre, rubber, or leather, depending on the service. Ball-valves may be steel, bronze, or rubber-covered iron, with bronze or steel seats. Valve-seats are turned on a taper outside to facilitate insertion or removal from the decks in the valve-chambers. All valve-openings are designed for a water-velocity not exceeding three feet per second. Special attention is given to the question of lubricating all parts of the Superpump. The means range from the ample grease and oil-cups of ordinary requirements to elaborate force-feed systems actuated by the crankshaft for large heavy-duty units.

EMPLOYEES OF THE MINNEAPOLIS STEEL & MACHINERY CO. CELEBRATE THE NATION'S BIRTHDAY

The accompanying illustration shows an assemblage of skilled craftsmen listening to the reading of one of the imperishable documents that embody the spirit of Americanism. They are the men who operate the big plant of the

Minneapolis Steel & Machinery Co., gathered for a patriotic program in anticipation of Independence Day. Only a small part of the audience could be included in the camera's focus, but these men are representative of the whole. This picture is characteristic of the company's organization. There are few enterprises of its size in the country which boasts of more friendly relations, not only between employer and employee, but among the men themselves. Interdepartment friendships are cemented by summer kitten-ball leagues and an all-winter bowling league, picnics, and dances at the Minneapolis Steel Club, and the men are encouraged to take a personal interest in the company's welfare.

COMMERCIAL PARAGRAPHS

After August 1 the office of H. W. Clarke, manager of the publicity department of the Chicago Pneumatic Tool Co., will be in the Chicago Pneumatic building, 6 East 44th St., New York City.

The General Engineering Co., of Salt Lake City, has been retained by the Utah Consolidated Mining Co. to design and erect the 1000-ton flotation-plant that the mining company is building at Tooele, Utah.

Bulletin 504, recently issued by the Chicago Pneumatic Tool Co., 6 E. 44th St., New York, describing its Slogger rock-drill, is now available, upon request, from its New York office or any of its branches.

On August 1 the Denver Rock Drill Manufacturing Co. opened a new branch office at 421 Manhattan Bldg., Duluth, to facilitate the handling of its business in the Minnesota and Michigan districts. The new office will be an added convenience to the company's customers.

The Republic Belting Co., of Baltimore, has acquired a site covering a full city block for the erection of its new plant. Mr. Haldreich Egli has been retained to direct the construction work, which is to be commenced at once. Charles H. Dankmeyer, president of the company, has been engaged in the belt-manufacturing business for many years and his organization will include experienced men in their particular line.

The Buffalo Forge Co. has issued catalogue No. 700 on 'Fan Systems of Heating and Ventilating'. The company has always taken the stand that engineering data and developments should not be hoarded as hidden treasures but should be made available for the use of the engineering profession in general. In this volume it has laid stress on the principles underlying all the various steps in the determination of suitable apparatus to meet all conditions of heating, ventilating, and humidifying. These principles have been proved by actual practice and are the ones used by its own engineers in the solution of problems of a similar nature. This is a most valuable publication for the ventilating engineer as a reference work dealing with the principles of ventilation and the most modern equipment.

D. D. Tripp, vice-president of the Pioneer Rubber Mills, returned some time ago from a five-months journey in the Orient. He says that his trip proved resultful in the actual contracts secured, in the new agencies opened for the Pioneer Rubber Mills, and especially in the intimate insight he had obtained into conditions in the Orient. His company is making adequate plans to take care of its increased domestic and foreign business and, to this end, has materially enlarged the capacity of its plant at Pittsburg, California. One of the largest and most modern belt-presses in the United States was recently installed at the plant. It is indicative of the progress made by this Pacific Coast institution, not only in broadening its market but in taking good quality-care of its business at home.

TANGIBLE evidence of the unfortunate result of the steadily increasing cost of producing gold is found in the recent action of the Tonopah Belmont Development Company in suspending all operations except pumping at its Shawmut mine in the Mother Lode region of California. Last January the ore-reserve in this mine was reported to be 429,098 tons, so the reason for the action of the directors is obvious.

BENDIGO was once a name to conjure with, but that was long ago. Like other mining communities born in the golden age of Californian and Australian discovery, its glory has grown dim; yet it remains an important and attractive town, thanks in part to a prosperous agricultural industry. The golden grain on the surface now brings more riches than the harvest of gold underground. Even this is not ended. We learn, from an Australian paper, that on May 26 a shipment of remarkable ore was made from the Constellation mine, belonging to the Bendigo Amalgamated Goldfields. It is reported that 365 tons broken on the 622-ft. level yielded 1465½ ounces of gold. Since the 'reef' was found 18 months ago a profit of £100,000 has been made. The 'reef', of course, is not like anything the term suggests, but a 'saddle', an anticlinal structure of gold-bearing quartz following an arching fold in the slate and sandstone beds of the Lower Silurian sediments. In 1853 Bendigo yielded 661,729 ounces of gold, worth about \$13,250,000. Altogether Bendigo's output is estimated at \$325,000,000. In 1917 it contributed 66,000 ounces.

WE have received a copy of a prospectus in which is described a new kind of ore deposit. It consists of "a lime-quartz dike or belt several thousand feet wide". Of course, it is of no importance whether the width be two or twenty thousand feet. It has "a very peculiar asbestos grain or texture". It must be peculiar indeed. "Almost the whole of this dike carries values in gold and silver with occasional carbonates of lead." For our part we prefer the "carbonates", which are specific, even if "occasional", to the "values", which are nebulous. What is or are 'values' anyway, for the love of Pete? The prospectus quotes no assay; it gives no average contents; it expatiates only in terms of 'values'. "Occasional lenses of this asbestos character", we are informed, "carries very high gold values, the lead being dissipated

almost entirely". Why not? What's to hinder? We quote *verbatim et literatim*. Apparently "the character carries very high gold values", which is reasonable, for one abstraction may well be contained within another; it is more reasonable than putting a concrete idea within one that is abstract. That would be dyspeptic to any real philosopher. Shades of Metalliferous Murphy! how he would love the lead that is "dissipated entirely". "The geological formation shows very deep and lasting bodies of ore values". A body of "ore values" resembles the limited liability companies, of which it has been said that they had no souls to save and no bodies to be kicked, and thus were free in this world and the next from all the effective sanctions of conscientious conduct. People who talk about exploiting "ore values" in a lime-quartz dike, or any other geologic abortion, enjoy the sensation of thought without the trouble of thinking.

GOVERNOR COX, in his speech of acceptance as the Democratic nominee for the Presidency, strikes a note that is more natural, and therefore more interesting, than that of his opponent. Indeed if speech-making be the main test of fitness for the most responsible office in the world, Senator Harding is disqualified. Both candidates take much the same stand on the various issues, except the League of Nations. On that they cross swords unmistakably. It is a great and vital question, and we are not sorry to see it made the chief issue of the political campaign that is now formally started. A separate peace with Germany is unthinkable, for it would dishonor us as a nation and involve us in complexities worse even than those that face us now owing to our refusal to ratify the peace that has been made by our Allies, or Associates. That the League should be used only for maintaining peace and that our participation must be within the terms of the Constitution are 'interpretations' in which every citizen can well afford to join with Mr. Cox. We agree with him that "we are in a time which calls for straight thinking, straight talking, and straight acting", in short, we must be true to our traditions—those handed down to us through Washington, Lincoln, and Roosevelt.

UNDER the caption 'An Inside View of Wall Street' we are told, in the 'Boston News Bureau', that "the Harding letter of acceptance is the most forceful document of its kind that voters have read in recent years".

This is true only if voters do not make a habit of reading such 'documents'. But we can understand that it pleased certain people on Wall Street and State Street. Harding promises, from their point of view, to be 'good'. Editorially the same useful financial paper says: "The art of clear and graphic statement is one of the marks of a leader of the people". This introduces sundry favorable remarks upon Mr. Coolidge's letter of acceptance, which certainly was vastly superior to that of his colleague, but even so is nothing to brag about. Why in thunder do not these gentlemen talk plain English and avoid their foolish efforts to be impressive not by clear thinking but by a stilted magniloquence. Front porches seem to be more demoralizing than pulpits and almost as debilitating as soap-boxes. Our Boston contemporary says that Mr. Coolidge's speech is "a powerful, but characteristic, complement to the longer, more detailed and argumentative utterance of Harding". It is astonishing how the faculty of criticism is benumbed by partisanship, and how clever people like Mr. C. W. Barron, of the 'News Bureau', are not content to fool themselves but expect to extend the process to others. Most of the time they succeed with most people.

SOMEbody has sent us the prospectus of the Broken Hills Silver Corporation, together with a letter mailed to him by George Graham Rice. Our correspondent has taken care to remain anonymous, by cutting out the place where his name and address had been written. Evidently he assumes that we shall show more moral courage than himself. His assumption is fully warranted. Whether the mine under option to the aforesaid corporation is valuable or not, we do not know. The report by Mr. A. P. Thompson is not convincing. There is too much geologic guff; the quantity of it is wholly disproportioned to the number of assays quoted or the amount of real information conveyed. Mr. Thompson says that the property lies in "a region of profound volcanic disturbances", although most of his remarks deal with surficial lava and "cap rock". There is too much pseudo-scientific stuff, such as: "East of this strata [stratum, if you please, but even that is not the word for a flow of andesite] of silver-bearing silicious andesite, more basic andesite flows cover the surface. While there is no evidence either on the surface or underground in the mine to definitely fix the age of this andesite relative to the more acidic rock, in which most of the veins and ores [are the 'ores' detached from the 'veins'?] occur, it is possible that beneath this basic andesite the more prolific mineral-bearing acidic flows will be found." This reads like a front-porch speech by a politician trying to avoid saying anything by talking a great deal. Mr. Thompson says that "vein-matter which does not contain 100 ounces silver per ton or over is left in the workings and used as a floor". What magnificently negligent persons the present owners must be! He cites the assay of a sample here and there, but he does not quote the results of systematic sampling, although he appears to have taken some of his samples "at intervals of ten feet". In approved front-porch manner he makes the sapient remark:

"In the course of stoping the ore it will be convenient and highly desirable to sort out the barren rock from the ore in the stopes after it is broken and before the ore is hoisted to the surface." Who would have thought it! He finds \$101,375 of ore blocked out, with various possibilities and potentialities, some of which are not unreasonable in an area so well fissured and mineralized, but this prospect is capitalized for 3,000,000 shares of 10 cents each, of which 2,000,000 shares have been underwritten by the Fidelity Finance and Funding Company of Nevada "to net the Broken Hills Silver Corporation \$380,000". This sounds grand; but it is only another name for Rice, *alias* Herzig, who signs the letter as Treasurer and whose nefarious doings have been exposed time and again. He calls attention to a copy of "a commendatory letter from the Chief Executive of the State of Nevada, which appears on page two of the circular". Now, Mr. Emmet D. Boyle is a mining engineer and a first-rate man in other respects, but it is fair to ask why he allowed his name to be used by such a man as Rice, whose career as a fake promoter is notorious. Moreover, we venture to say that for gentlemen labeled as "The Treasurer of the State of Nevada" and "The State Bank Examiner of Nevada" to use the prestige of their public office to boost a promotion by Rice is a scandal. In any event, we are surprised at Mr. Boyle. He gives his opinion of the mine after an examination that he describes as "necessarily cursory". He might do this as Governor of Nevada, but he ought not to do it as an honorable member of the mining profession.

COPPER in the form of large masses of native metal is found in the amygdaloid lodes of the Lake Superior region. Our correspondent at Houghton records the fact that a mass weighing 24 tons was hoisted recently through the No. 2 shaft of the old Quincy mine. Last year 1290 tons of 'mass' copper was hoisted through this same shaft. The latest, weighing 24 tons, was 8 feet long, 4 feet wide, and 4 feet thick—in other words, just the size of a cord of firewood. In order to get it into the skip it had to be cut into three pieces by means of an acetylene torch. In the old days the cutting would have been done by means of chisels and hammers. The largest mass of copper on record was the one found in the Minnesota (with one 'n') mine, in the Ontonagon district of Michigan, in 1857. Its extreme dimensions were 46 feet long, 18½ feet wide, and 8½ feet thick, that is, as much as 60 cords of wood. It weighed 420 tons, which suggests that it was ragged in shape and that the extreme dimensions do not indicate correctly its real bulk. Attempts to break it by blasting failed ridiculously, as might be supposed. Then 20 men labored with cape chisels (having a ¾-inch bit) and sledge-hammers for 15 months; the cutting yielded 27 tons of chips. The cost of cutting was \$12 per square foot. In later days the pneumatic hammer has been used successfully, at about a quarter of the cost of the old-fashioned method. We shall endeavor to ascertain the cost when the acetylene torch is used for the purpose, as mentioned above. The latest mass was unearthed on the 82nd level of the Quincy. As the shaft

follows the dip, which flattens from 50° at surface to 37° in the lower workings, the 82nd level must be about 5000 feet deep. It is an interesting fact, but not discordant with scientific expectations, that native copper in large lumps should be found a mile below the surface.

The Examination of Mines

In this issue we publish another of the series of articles by Mr. Morton Webber upon the sampling and valuation of mines. This time he describes the system he himself uses when engaged in the task of appraising a large mine. Of course, his methods are not unique; in large measure they resemble those of other experienced mining engineers, but the description of the plan he adopts will pique the curiosity of his peers and should prove highly interesting and useful to the younger members of the profession. It is proverbially difficult to teach new tricks to an old dog; probably Mr. Webber's contemporaries will prefer their own way of attacking such a problem as the one described in his article, but his juniors will be grateful for this frank and detailed account of the practice followed by a successful senior in their profession. After all, the generalized statements and roundabout ratiocinations to which many writers limit themselves may have a vague literary charm, but such a frankly egoistic account as Mr. Webber's brings the engineer face to face with realities; it gives first-hand facts in a way that the practitioner in the field, rather than the student in the library, will be glad to use to his own benefit.

It will be noted that Mr. Webber is willing to avail himself of the assistance of the geologist, but he has a decided opinion concerning the limitations of the latter as an appraiser of mines. We are in accord. Some, but not many, geologists have had the training of a mining engineer, the best of which is the actual management of mines, but commonly they lack the qualifications for valuing mines, and many are the sad stories of those unaware or careless of such qualifications. The geologist naturally is as strong on the scientific side as he is weak on the commercial; he knows the value of geologic criteria much better than he appreciates the incidence of economic conditions upon the profitable exploitation of an ore deposit. Mr. Webber shows good judgment in recognizing the proper province of the geologist and the unwisdom of a mining engineer on his part attempting to elucidate geologic relations vital to the future of a mining enterprise without the aid of a specialist in that subject. Next Mr. Webber lays emphasis on the fact that wise men do not buy mines for their ore-reserves—they do not buy ore—but in the expectation of an expansion of the enterprise through the finding of more ore, in depth or laterally; they hope to do better than the previous owner by the application of more skill, in management, in mining, or in metallurgy, than the other fellow could command; or by the lowering of the cost of winning the metal by increasing the tonnage treated, either by additions to plant, by more extensive development, or both. In plain English, the buyer expects to

do better than the seller; it is a speculation, based upon technical data plus luck, for a man who goes into mining without casting a kindly eye at a billiken or some other fetish of good fortune does not know the proper spirit of the adventure. An adventure it was and ever will be, from Colchis to Chuquicamata. In starting an examination one has to deal with men as well as samples. Mr. Webber touches upon the amenities of the business. He who does not understand his fellow-men is likely to make blunders, or, at least, to lose many opportunities for obtaining hints that are worth as much as a thousand assays. The object of an examination is to value the mine, of course, but to do that comfortably it is also desirable to understand the vendor's standpoint and to ascertain why he is selling. In other words, the canny engineer will look around for the nigger in the wood-pile, for any condition that while explaining the motive for the sale thereby gives a reason for not buying. That applies especially to high-grade mines and to those that have been too little tested by metallurgical results. In the days of our forefathers it was customary to depend less upon sampling and assaying, and more upon other kinds of evidence of an unsystematic character. The graduate from a mining school today has been taught how to sample and survey, how to map and estimate, he has heard of amortization and Inwood's tables, but with all his meticulous methods he may fail lamentably in recognizing the real character of the mining venture on which he is asked to express an opinion. His grandfather, if in the same profession, would have looked over the records of the mine, examined the maps, gone underground, broken a sample here and there, recognized the critical headings, and put his finger on the vital spot. He did it unsystematically, partly by sheer native intelligence, partly by a knowledge based upon experience, sometimes by a stroke of luck. At other times, he failed lamentably in his appraisal, just as his much better trained grandson. A good judgment on a mine, or on anything, requires the ascertainment of facts, the elimination of the non-essential, the concentration of thought upon the essential factors, and then the ability to put them in their right relations. On the whole, the best thing to do is to become friends with the foreman, if he is intelligent; if not, then give a cigar to the shift-boss.

Engineering Education

Recently we received a circular from Columbia University that outlined graphically the requirements of the various engineering courses based upon six full years of instruction after the high-school. The first three years of this work may be done at any of the better colleges by making an appropriate choice of subjects. The course in mining engineering at Leland Stanford University has also been lengthened to six years, but so far as we know these are the only institutions definitely requiring six years of university work, although there has been much discussion of the question and considerable agitation in favor of such a change. To some extent this is due to a growing conviction that engineering curricula should in-

clude more of the cultural and economic subjects rather than be confined almost exclusively to purely technical studies. This idea, we believe, is eminently sound. If, then, it be granted that philosophy, economics, English literature and composition, and perhaps some of the more practical subjects, including industrial organization, business law, and finance, should have a place in the college training of an engineer, we are faced with two alternatives, namely, either to cut down some of the technical courses that hitherto have occupied all of the time in the regular four-year period, or to lengthen the period of the standard course by one or more additional years. Some who favor a lengthened course declare with great conviction that "four years of college work is not sufficient to make an engineer". They speak more truly than they know, for six or even a dozen years in college cannot and will not make an engineer. With respect to mechanical and electrical engineers, this view of the matter may not apply with equal force, but a mining engineer is not the product of any school; upon the completion of his college course he is simply equipped to make an engineer of himself in the minimum possible time. We are prepared to concede that at the end of six years of college work the young man is better qualified than he was at the end of only four years, but whether it would not be better for his career, as an engineer, to have devoted the last two years to the actual practice of his profession, is a moot point. Whenever this question is discussed a comparison is invariably made with the established curricula of six years for the training in medicine; there appears to be lurking in the background the feeling that the dignity of the engineering profession suffers somewhat from the implied reflection that it can be 'learned' in a shorter time than that of our medical friends. This, of course, is no argument in favor of a lengthened engineering curriculum; there are, on the contrary, distinct differences that make an excellent reason for a longer course in the school of medicine. The diseases and the symptoms, and perhaps, to a less extent, the cures, with which the physician comes in professional contact are unchanging. Much of his time is spent in clinics where the identical processes and operations that necessarily will form part of his future work are being performed; and moreover, he is, early in his career, called upon personally to assume the responsibility for human life. Fortunately, it is practicable to train the doctor in the college and its affiliated hospital. The work of an engineer, the mining and metallurgical engineer in particular, is different. His problems are constantly changing; entirely new conditions are met and have to be overcome; no two tasks are alike. His schooling therefore is not to teach him by practice how to do certain definite things, but to equip him to use ingenuity, resource, and judgment in applying science and art to the solution of new problems under varying sets of conditions for the purpose of achieving definite economic results. What then should a college course in mining engineering include? We suggest a sound broad foundation of mathematics, physics, chemistry, geology, mechanics, economics, and English, with a supplementary teaching that will

show the relation of these subjects to mining and metallurgical problems. A valuable course would be one in which were given hypothetical problems involving ore deposits of specified character and composition that are to be mined, milled, and smelted. The solution might consist, not in a detailed practice to be followed, but in a general outline of the processes to be used, with references to the books in which data on each process are to be found. We submit that a man who has never been in a mine can study mining methods from a book for a year and learn less than he could from the same book in a week after he has spent six months working as a suveryor or sampler underground. The young mining engineer almost invariably is so situated that he has an excellent opportunity for study, and if he does not take advantage of it he is not the kind that will develop into a successful engineer. A book on copper-smelting or one on mine-sampling becomes tenfold as intelligible after a man has run furnaces for a few months or assisted an experienced engineer in examining a mine. The proposal is not to discard such studies from the curriculum; but the question arises, is there wisdom in trying to absorb a great mass of detail in a dozen different arts, many of which are undergoing constant change, and few of which will concern in detail the work of any particular graduate. The ambition of the student in mining engineering usually is to become a manager or executive, or to specialize in some one particular branch with a view to practising as a consultant. However, the average youth does not have a definite idea as to just the work for which his tastes and abilities will best fit him; in fact, until he has been engaged for a time in actually doing things, he is in no position to make a decision as to what to choose as his future work. If he is a handler of men, and his judgment is particularly sound, he will doubtless become an executive; college training in economic and cultural subjects will be of particular value to him; in the future, experience will be his best teacher. If, on the other hand, it develops through chance or otherwise—and we cannot honestly deny fate a considerable measure of influence in these matters—that the young engineer becomes a specialist in a given kind of work, the detailed information regarding a dozen other subjects that he may have accumulated will be of slight value to him. It is quite possible that he may be able to take a year of post-graduate work, in which case his efforts will be directed intelligently toward a definite end. We can appreciate the reasoning of those who think that in either case a four-years college course supplemented by two years of experience would have accomplished more toward ultimate success than six years spent at school. In the end the purpose of an engineering education is to develop clear thinking, good judgment, and the ability to apply scientific principles to the manifold forms of industry. Whether this can be done most effectively by giving a four or a six-year course in our engineering schools, and in either case, what kind of curriculum should obtain, are questions permitting sincere difference of opinion. We welcome discussion on any phase of the subject.

DISCUSSION

Two Suggestions on a National Problem

The Editor:

Sir—It seems to me that it is no use for this country, or any other, to fool itself into the belief that the oil and gasoline problems will be solved automatically; everything points to the reverse. In the United States, even though the production of petroleum increases each year, yet the known resources have been determined by the Geological Survey to be only a matter of a couple of generations. In the meantime, stocks have dwindled to a small quantity when compared with those of five years ago; while the uses of oil and its products are extending rapidly. In five years, the Pacific Coast States report a gain of 200% in the number of automobiles and trucks, and 400% in tractors. It is pretty safe to say that the increase in other States has also been large. I was in the East for six months in 1917-'18, and for ten months in 1919-'20, and noticed how many more motor-cars and trucks were in use. And this factor will continue to be an increasing strain on the oil industry. More engines of the Diesel type are being used, and, as D. M. Folsom remarked in an address before the American Mining Congress in San Francisco in January 1919, "the heart of the hydro-electric systems in California is the steam-plants in the cities, where power is generated by oil-fuel". It is not intended here to discuss hydro-electric power, simply to say that the new Water Power Bill should hasten development of the remaining forty millions of horse-power available, and eventually dispense with steam-plants.

Regarding the gasoline problem, the prime causes of the present position were ably discussed in the 'Press' of May 20, 1916, by J. H. G. Wolf. The intervening years have accentuated the trouble. Something has to be done, and I doubt whether the many lower grades of distillate or various forms of alcohol will be effective. As a substitute for gasoline or distillate for automobiles and trucks in urban areas, I have suggested city gas. According to Captain Brewer, who addressed the Engineering Societies in San Francisco a couple of years ago, during the War, some automobiles in England used city gas, which was stored in an unsightly bag atop of the machine. This gas was at low pressure, supplied by gas-works. My suggestion is to compress the gas to several hundred pounds, store it in a receiver on the machine, and pass it through a reducing-valve before use. Supply-stations could be provided, just as they are for gasoline. I communicated my idea to the Ford Motor Co., whose research department said it was not a practical solution of the

problem; also to John A. Britton of the Pacific Gas & Electric Co., who has not replied yet. As if refuting the Ford reply, I find that in England the Government has been investigating the use of the Smith gas-producer on motor-trucks, as a substitute for petrol (gasoline) and other oil products. The Army authorities declare that the system is entirely satisfactory, and at the lowest known fuel cost, in this case coal at 55 shillings (\$13.20 per ton normal exchange) producing gas equivalent to petrol at 3.4 pence (6.8 cents) per gallon.

Regarding the tremendous quantity of oil used under boilers to make steam, the number of stationary engines consuming gasoline, distillate, and low-gravity petroleum, and the tendency to increase the number of Diesel engines, I have advocated the use of producer-gas engines wherever possible. I have communicated my ideas to the Skandia Pacific Oil Engine Co., of Oakland, California, where I recently saw an 1100-hp. Diesel engine undergoing a test; the Union Gas Engine Co. of Oakland; and F. G. Cottrell, Director of the U. S. Bureau of Mines. The producer-gas type of power-plant is extensively used in Australia, England, and the Continent of Europe, and after studying its efficient use in the Western States, I wrote an article in July 1910 for the 'Mining Journal' of London.

Although the use of small producer-gas engines has not advanced in America, there are a good many large engines in the Eastern States being driven by blast-furnace gas; and I believe that the Ford Motor Co. at Detroit employs engines consuming city gas. Incidentally, I might mention another use of producer-gas: that being in the Humphrey gas-pump. By means of an explosion-chamber, and a large 'play-pipe', in which water can surge to and fro, enormous quantities of water are pumped, but through low-lift. Instances are those pumping 180,000,000 gal. daily for the water-supply of London, and also near Cairo, in Egypt, lifting 300,000,000 gal. daily for irrigation. In Australia this type of engine is used, up to 500 hp., for all kinds of work, competing with electric power. The fuel used is almost anything—coal, coke, charcoal, sawdust, sugar-mill refuse, sawmill refuse, and firewood up to 6-ft. lengths. I saw most of the seventy-odd engines then at work, producing 3400 hp., and heard little complaint regarding their behavior; and certainly none on the score of cost, then about one penny (two cents) per British horse-power for all charges. At Waihi, in New Zealand, a large producer plant, using coal, supplied gas to a number of 200-hp. engines, and the total cost was only 6 pence (12 cents)

per horse-power. I cannot see why the enormous quantities of waste from all industries in America, the low-grade fuels (even the coal of California at Tesla and Coal Canyon), the peat of North Dakota (Canada has already investigated its peat for this purpose), and many other combustibles should not be used in producers to make carbon monoxide for engines, and thus conserve the oil-supply and avert a crisis. For this reason I suggested to Mr. Cottrell that the Experiment Station at Pittsburgh make trials on such engines using the fuels mentioned. This is not only a national problem; it is international, and all oil-men are aware of it. I give my ideas for what they are worth.

MAX VON BERNEWITZ.

San Francisco, August 1.

An Interesting Experiment

The Editor:

Sir—There are several possible explanations for Mr. Gardner's experiment with gold foil and mercury, but just the same "it reminds me of away back when" we read the story of the scientists who discussed why it was that when one filled a bowl with water and then put in a stone the water overflowed, but when a fish was put in, instead of the stone, the water did not overflow, and after discussing the question for several days one of them thought to test the statement, so the bowl, the water, and the fish were brought together and the experiment tried, only to find that the water *did* overflow.

I am not contradicting the observations recorded by your correspondent, but only refer to them because the points involved are not definitely stated and we may be discussing something that 'ain't so'.

The first explanation is siphoning by capillarity. If the outside end of the gold foil is below the level of the mercury in the container, this will take place. If gold foil is dipped into mercury, the mercury will be drawn up on the gold foil to a point regulated by the attractive force between the mercury and the gold, the physical condition of the gold foil, and the static head of the mercury above the level of the bath. If the point to which the mercury will rise under the condition of the test is higher than the top of the siphon, the mercury will pass over and down the outside portion, and the amount of mercury on the side of the shorter leg of the siphon will be such that the attractive force of the mercury for the gold is just balanced by the weight of mercury sustained. Equilibrium will be reached when the same condition is reached at *C*, if the foil ends at *C*, but if the foil extends to a point below this, say *D*, the mercury will be drawn on to *D* and at this point the static head will be greater than the attractive force and it will drop off at a rate governed by the height of *B*, the temperature, condition of the foil, and the length of *CD*. Try this with a string and a glass of water, remembering that a certain length of *CD* must be allowed to compensate for the dryness of the atmosphere.

Mr. Gardner states that the levels *A* and *C* are the

same, but as that is a condition almost impossible of attainment under the circumstances, he must be speaking generally. If the end of the foil is below *C* the above explanation is ample. If it is at or near *C* the explanation may be similar but due to inequalities of conditions. In the latter case equilibrium would be reached when *C* is supporting the maximum weight of mercury. If the apparatus is set up near a stamp-mill or dredge the vibrations might jar a small drop loose on the outer end yet be dampened by the bath on the inner portion. Similar conditions might be brought about by change of capillarity constant due to temperature variations.

Another explanation is that if the end of the foil is at

DIAGRAM SHOWING CONDITIONS OF THE EXPERIMENT

or near *C* and equilibrium reached, the mercury need not be saturated with gold. On standing, this would take place and both increase the amount supported and decrease the attractive force, with the result of the loss of a drop. The drop would be replaced by another unsaturated and this action taking place along the line result in a constant motion toward *C* until the gold is dissolved. This would explain why the action would not take place under water.

If the end of the foil is above the point *C*, I am inclined to believe it another case of the fish and the dish.

PHYSICIST.

San Francisco, July 30.

THE BUREAU OF MINES has recently published Technical Paper 229, 'Accident Prevention in the Mines of Butte', by Daniel Harrington, mining engineer for the Bureau. Mr. Harrington, in the course of an investigation of the health and safety conditions in the Butte district, conducted by the Bureau in co-operation with the U. S. Public Health Service, personally inspected practically every working-place underground in many of the mines of the district. In the investigation it was found that in nearly all the mines where much attention had been given to accident prevention, the results obtained were commensurate with the effort expended, not only in decrease of accidents of all kinds, but in the large saving to the companies in dollars and cents. The report describes in detail the safety organization and work of the several companies, gives statistics on the accident rates in Butte mines for the years 1915, 1916, and 1917, and presents conclusions and recommendations based on the results of the investigation. Copies may be obtained free from the Bureau at Washington.

The Bunker Hill Enterprise—XI

The Use of Electricity in the Operations of Mine, Mill, and Smelter—II

By T. A. RICKARD

The electrical energy used underground is delivered at 2300 volts, three-phase, at a point near the collar of the No. 1 shaft. The first cable for transmitting electricity underground was laid in 1906 in the Kellogg adit; it was covered with lead, without any jute or other armor, yet it has given uninterrupted service along the 10,000 feet of transmission. The second cable, parallel with the first, was laid in 1911; this has a double wrap of jute, in reverse lay, for protecting the leaden sheath. Both these cables are supported on a $\frac{3}{8}$ -in. Siemens-Martin galvanized strand, using Boston clips with zinc straps that go

sufficient to provide against any interruption of electricity to the pumps or hoist in the event of an accident in the adit. In 1918 a third cable was laid in the Reed adit, two miles south of the Kellogg portal. This last cable was furnished by the Standard Underground Cable Co. and is especially designed for the purpose. It is of

W. J. LOCKE, MINE ELECTRICIAN

TRIPPING-DEVICE ON SWITCH, WHICH OPERATES FROM AUTOMATIC TELL-TALE, DEVISED BY M. J. BOTTINELLI

around the cable. The clips are spaced about 18 in. apart. The strand, or 'messenger', is supported on L hangers that are bolted either to timbers or to expansion bolts ($1\frac{3}{4}$ in. diam.) flattened and drilled on the exposed end for receiving the hangers. In addition, the messenger is attached to eye-bolts with bridles every 500 ft., so as to take the strain each way and prevent slack in case the messenger itself should break.

The two cables have a combined capacity of 800 hp.,

the three-conductor type and 6000 ft. long, each conductor being insulated with $\frac{5}{64}$ -in. varnished cambric. A lead sheath, $\frac{1}{8}$ in. thick, serves as a protective cover against moisture and acid. This in turn is covered first with a layer of jute, then by No. 6 galvanized steel, and finally with jute. The insulation is designed for a constant pressure of 3000 volts.

This cable weighs 5 tons per 1000 ft., so it was ordered in lengths of 500 ft. and on special reels small enough to

fit the mine-openings. In raises, or wherever the cable has to be hung at an angle, special joint-boxes are used. A sleeve, 7 in. diam. and 30 in. long, with brass flanges and plugs, is attached to the joint in the cable. This sleeve is filled with a soft compound, which flows into the cable, thereby compensating for the loss (due to the natural downward flow) of the same compound with which the cable is impregnated when it leaves the factory. Before pouring the compound into the upper joint-box, it is heated to 250°F. for about 15 minutes in order to expel any moisture; it is then allowed to cool before being poured into the sleeve. At the bottom of the inclined parts of the cable, an inverted joint-box is placed, for the purpose of preventing moisture from entering the cable and to seal it by pressure so that the compound cannot escape. Previous experience with other cables had shown that the compound would leak out of the ends of vertical cables, thereby impairing the insulation. The factory price of the special cable was \$10,860 (in 1918, during the War) and the complete equipment, including the necessary raises, messenger wires, and other supplies, was \$17,500.

All the pumps in the mine are operated by electricity and each is provided with a recording ammeter, marking the time when it was started and stopped, as well as the power consumed. By a scrutiny of the chart it is possible to detect the condition of the mechanical parts, as, for instance, a loose or broken valve. The water of the mine is relayed from the No. 14 and No. 15 levels to the No. 13, from which it is pumped to the top of the shaft at the No. 9 level, or Kellogg adit. The levels are 200 ft. apart. The combined discharge from the pumps in both shafts is 804,750 gal. per 24 hours, or 506 gal. per minute. The mine-pumps consume 4145 kw-hr. per day at a cost of \$25.78, the cost per thousand gallons delivered at the collar of the shafts being 3.23 cents.

The first electrically operated pump was placed on the No. 11 level in September 1906. It was of the triplex horizontal type, with a capacity of 500 gal. per minute against a 400-ft. head, and was double-gearred to a 75-hp. Westinghouse C. C. L. motor. The cost of it was only \$1900. The second pump was placed on the No. 12 level in the summer of 1909. This was an Aldrich pump of the quintuplex vertical type; it had a capacity of 425 gal. per minute against an 800-ft. head and was geared to a General Electric 125-hp., 2200-volt, form M motor. The cost was \$3120. The third pump was placed on No. 13 level of the No. 1 shaft in 1911. This also is of the quintuplex vertical type, made by the Birdsboro Steel Foundry & Machine Co., in Pennsylvania. It has a capacity of 500 gal. per minute against an 800-ft. head and is geared to a G. E. 150-hp., 2200-volt, form M motor. It cost \$4300. On the same level, at the No. 2 shaft, there is another quintuplex vertical pump of the same design with a capacity of 550 gal. also against an 800-ft. head, and geared to a similar motor. This pump cost \$4920.

The shaft-stations on the No. 13 level are about a

thousand feet apart. A pump forces the water from one station to the other along the level. This is a horizontal three-stage centrifugal pump made by the Swaby Engineering Co. and has a capacity of 700 gal. against a 275-ft. head. It is direct-connected to an Allis-Chalmers 100-hp., 2200-volt, 1800 r.p.m. motor. The cost of this pump was \$1545.

The water from the lower levels is assembled at the No. 13 level, where a large sump is established for the purpose of storage. This sump, of course, collects mud, which has to be removed periodically. To do this a 10-stage horizontal centrifugal turbine-pump is used. It was made by the Byron Jackson company of San Francisco and has a capacity of 250 gal. per minute under 800-ft. head. It is direct-connected to an Allis-Chalmers 150-hp. motor. This pump cost \$3500. The cost of the various pumps as quoted here is f.o.b. factory and does not include the motors.

On the No. 15 level there is a seven-stage horizontal centrifugal turbine-pump made by the Byron Jackson company. It has a capacity of 270 gal. against a 410-ft. head and is direct-connected to a Westinghouse 50-hp. type CS motor. In addition, on this level, there is a four-stage pump of the same type made by the Cameron Steam Pump Works. This has a capacity of 400 gal. against 400 ft.; it is fitted with the Kingsbury thrust-bearings and direct-connected with a Westinghouse 75-hp. motor.

As an example of the hard usage to which electric apparatus is subjected underground, it may be stated that the third pump purchased by the company, and placed on the No. 13 level, was completely submerged under 200 ft. of water for three weeks, yet even after that experience the motor* was not disconnected from the pump nor the rotor removed before re-starting. The windings were dried by use of an electric current at low voltage furnished by the Curtis steam-turbine at the power-house operating at slow speed and by the aid of hot air-blasts from electric radiators assisted by electric fans. The fourth day after unwatering, the pump was started and has operated continuously since, showing no ill effects from the excessive water-pressure on the windings.

In a mill the use of electric power is advantageous, of course, on account of the small space required by electrical units and by reason of the extreme flexibility of such applications of power, the individual drives permitting the millman to shut-down any particular unit without interrupting the other units of a system. Constant speed is another obvious advantage afforded by electrical machines, which can be adjusted to a given speed and maintained at that speed, whereas if driven by gas or water the speed usually varies with the load. As engineers drifted from the direct use of the water-wheel and the steam-engine, they found that, with elab-

*The submergence of this motor was due to the fact that a fire at the top of No. 1 shaft cut off the pump-cable. The mine-fire started on October 7, 1912, and since re-starting the pump has been in continuous operation to this date.

ELECTRO-MAGNET OVER BELT-CONVEYOR

WELDING OF A CAST-STEEL KETTLE AT THE BUNKER HILL SMELTER BY AID OF THE ELECTRIC ARC

orate and expensive governors, they could get much better results from machines operating at uniform speed. Of such machines those operated electrically do the best work. Moreover, the use of electricity enables the millman to place the various parts of his equipment in the most convenient positions; for example, the magnet used to remove bits of steel in the ore before it goes to the crushers. This magnet had to be placed in a particular position in order to give maximum efficiency. See photograph. If a big piece of ore comes along it can push the magnet to one side, because the magnet is suspended by a sling, which allows it to resume its position once the obstruction has passed. Mill-men are familiar with the trouble given in starting an induction motor in a cold building, especially after a shut-down, with its thorough chilling of the grease and belting. Usually sufficient starting resistance is demanded from the manufacturer that supplies the motor, but in many cases this proves inadequate, so that at the moment of resumption either the motor or its starting equipment is taxed unduly. The Bunker Hill company has made it a practice to use only motors dependent upon external resistance, such as the M type of General Electric motors, where such duty is required. In a number of instances it has been considered advisable to substitute the water-rheostats to serve as a temporary means of accelerating slowly under extreme load as demanded under the conditions described. This method of starting may be deemed heterodox; it is used only in emergency to prevent shut-downs or delays, because the burning of the resistance units supplied by the manufacturer would prevent the starting of the motor and the excessive current taken through such resistance under the abnormal demand would cripple the motor. Mr. Handy, the superintendent of mills, was much impressed with this method of starting and frequently requested the electrical department to attach this type of water-rheostat to all motors operating under severe starting conditions, and where slow acceleration was desired, but Mr. Clark has been loth to do so on account of its rather crude form; instead he has requested the manufacturer to analyze the conditions with a view to providing the requisite apparatus. For instance, in any mill in which belting is used it is necessary often to put on a belt after lacing, by tying the belt to the rim of the pulley by means of a twisted rope and revolving the pulley very slowly so as to run the belt onto it. The water-rheostat enables this to be done comfortably, whereas the usual sudden starting, by means of the conventional device, makes it both dangerous and uncertain to do so.

The mills were illuminated electrically when first erected, but it is interesting to note the use of the Cooper Hewitt light (a mercury-vapor lamp) over the jigs and other machines where it is desirable to examine closely the feed and tailing, and be able to detect any given mineral in either. It has been found that by shifting these Cooper Hewitt lamps to different parts of the mill, without drawing the attention of the men, the efficiency of the supervision is increased. Recently the C 2 Mazda, or

'Daylight', lamp has been employed in similar places for the same reason.

At the smelter the fullest use is made of electricity; 108 induction motors, five electric locomotives, and three electric cranes are in service, the total motor-capacity being 3572 hp. Individual motor-circuits are provided with oil-switches that cut in ahead of the compensators so that repairs can be made without interruption to the main power-feeders. The electric system is sub-divided into a number of feeder-circuits, each terminating on a separate panel in the power-house. The main power-feeder comes to the smelter from the sub-station at the mine; it carries 13,000 volts, which is reduced at the smelter to 2300.

The most interesting application of electricity at the smelter is the Cottrell plant for precipitating fume. This plant has not worked as well as was expected, but the various difficulties have been fairly well overcome now, so that a 95% clearance is being obtained. As originally designed by the Western Precipitation Co., the structure was to have been made entirely of steel, but owing to the difficulty of getting structural steel during the War it became necessary to substitute brick wherever possible. This proved fortunate on account of the practice of adding water to the fume in order to expedite settling. The humidity has been increased by the use of spray in the chambers; this, in turn, has caused complications owing to the condensation of water in the 'treater' where the moist gases come into contact with the cold exterior. The resulting sulphuric acid has played havoc with the steel, so that the use of brick and cement has proved fortunate. All the steel parts that were exposed to the outside air have been destroyed in consequence of the corrosion caused by the moisture in the fume. The outlet-pipes and boxes have been replaced with wood.

The Cottrell plant consists of four sections, each of which has 64 pipes, of 12-in. diam., or a total of 256 pipes. In the centre of each pipe is hung a No. 10 jack-chain or a piece of No. 14 galvanized wire, at the end of which is suspended a 20-lb. weight, to keep the wire or chain taut. The wires and chains alike terminate on a common bus above each section, and this in turn connects, through suitable switches, with the rectifiers, where they are charged with 60,000 to 100,000 volts of direct current. It has been found advantageous to reverse the polarity of the current at frequent intervals during the day. The draft through the treater is downward; this aids precipitation, as the fume has to pass down the 256 pipes and close to the highly-charged electric conductors, the wires and chains, so that ionization ensues, and then precipitation.

The best results have been obtained under the following operating conditions: The nine roasters produce 125,000 cu. ft. of fume consisting of about 10% solid and 90% gas. This product enters a humidifying chamber, 33 ft. long, 16 ft. wide, and 34 ft. high, in which are placed four baffles, alternately hanging from the ceiling and standing upon the floor, but not extending to the full dimension of the chamber, so that the fume, traveling at

the rate of 14 ft. per second, is compelled to circulate around them. It enters at a temperature of 220°F. and is cooled in the chamber to 110°. On top of this chamber there are 150 nozzles, made by the Spray Engineering Co.; of these, only 70 are used at any one time. Water is supplied under a pressure of 225 lb., the 70 sprays using 36 gal. per minute. The average humidity of the fume, as it leaves the chamber, is 45%. It is further cooled about 10° while going through the treater, passing down the pipes at a speed of 8 ft. per second. An interesting fact has been noted here: after the water was added to the fume the lead content of the precipitated material increased 10%, as compared with the composition before humidification was adopted, whereas the silver content dropped 30%.

As for the electric current itself, this is generated at

interruption in the delivery of power, and no failure on the part of the Bunker Hill company's equipment, for more than two hours since the start 17 years ago. The present sub-station is of the outdoor type; it is equipped with three 1800 kva. transformers, stepping down from 60,000 to 13,800 volts. The transformers are oil-cooled and are equipped with disconnecting switches so that in case of trouble any transformer can be separated for inspection and repair.

In closing, I like to instance another beneficent use of electricity, even though it be on a small scale, namely, the Clague electrolytic method for the treatment of lead-poisoning. The accompanying photograph shows three smelter-hands undergoing treatment at the Wardner hospital. At times as many as 40 men are being treated for lead-poisoning at this hospital. The treatment consists

ELECTROLYTIC TREATMENT FOR LEAD-POISONING

220 volts A.C. single-phase and is stepped up to the high voltage (60,000 to 100,000) required for the treater in special General Electric transformers, after which it is rectified. For the four sections of the plant there were supplied three rectifier units, complete with the motor-generator sets and transformers. It was planned originally to use one generator set on two sections of the treater and keep one set as a spare. Experience proved however that one unit operating in all four sections did just as good work as two units could do, and at half the cost for current; in other words, the load on a generator unit is not increased by the addition of two sections. The treater is so designed that the dust is allowed to settle in a chamber at the bottom of the pipes. Twice each month the dust is collected and sintered in the treater.

The electricity is obtained from the Washington Power Co. at a cost of \$36 per hp. per annum, this being the equivalent of \$0.00625 per kw-hour. At the outset, in 1903, the rate was \$88 per hp-year. There has been no

in passing a weak electric current (110 volts, D.C., 75 milli-amperes) through the patient's body while his forearms and feet are immersed in tubs containing a normal (0.7%) salt solution. The treatment lasts one hour. As yet no research has been done to ascertain whether there is any actual withdrawal of lead from the body, but a marked improvement in the symptoms is noticeable after about five such treatments, this result being more rapid than when adopting strictly medical treatment. Experimental work elsewhere appears to disprove the idea that there is an actual deposition of lead on the electrodes in the bath-water. Lead-poisoning is likely to become chronic if repeated; the acute symptoms will disappear in a few days, but complete recovery is a slow business. This electrolytic treatment, like any other cure for lead-poisoning, must be continued for some time, but it appears to be more rapidly effective than any other. It is of special value as a prophylactic, and if used early it will prevent a severe attack.

Signaling Mine-Hoists From Moving Cages

By C. A. ALLEN

The problem of signaling to the hoisting engineer from a moving cage has been considered by many mine operators for a number of years. There are several methods in use in different mining districts, but so far as the writer is aware they have been further developed in Utah than in any other State. The latest devices are of interest because they use a low-voltage circuit for the shaft-wires and also because the wiring can be so arranged that the hoist can be stopped from the cage, if so desired. The first installation in Utah was in the shaft of the Centennial-Eureka mine under the management of C. E. Allen. It was placed in operation in the summer of 1899, and has been in continuous and satisfactory operation for 21 years. The arrangement consists of two bare wires down the shaft carrying a current at 60 volts, with a device on the cage for making connection between the two wires. This device is simply a short piece of wire which is thoroughly insulated from the cage and is operated by a short lever. Whenever the cage-rider wishes to signal the engineer he pulls down the lever, forcing the short wire out against the two bare wires, thus making a circuit which rings the bell in the hoist-room. A similar device was placed in the Grand Central shaft at Mammoth, Utah, but was later abandoned. The cause of failure was reported to be that the shaft was very wet.

At a later date a system having the same general arrangement as that used in the Centennial-Eureka mine was placed in the shaft of the Eagle and Blue Bell mine at Eureka, but dry batteries were substituted, reducing the voltage to about 10 volts. This shaft is wet in places, but no trouble has been experienced. In order to give a better idea of the possibilities and application of the system, it should be stated that the hoist is a double-reel modern electric hoist with oil-operated clutches and brakes. The clutch and brake for each reel are actuated by different movements of the same control-lever. The hoist has the usual safety devices, such as limit-switches in the head-frame, position-switches for each reel, and ball-governor control. These devices are operated by what may be termed the control-wiring, which is in series with a no-voltage release on the switch-board. Should the circuit in the control wires be broken, the no-voltage release acts, which cuts off the power and automatically applies the brakes.

In the Eagle and Blue Bell shaft there are two No. 4 bare copper wires, one on each side of the shaft-guides. One of these wires is used for signaling from the levels, the second wire forming the return. The second wire is also used to make the circuit for ringing the bell from a moving cage. As regards signaling from the cage, it may be assumed that there is only one bare wire in the shaft, this wire extending into the hoist-room and through an ordinary Western Union relay-switch to the ground. On

the cage is a battery of six dry cells enclosed in a piece of iron pipe for protection. One terminal of the battery is connected to the hoisting-cable and is thus grounded through the hoist. The other terminal is connected with an ordinary push-button switch and a piece of curved copper plate which, by means of a small lever, can be pushed out against the bare wire. The push-button is on the same lever. When the cage-rider pulls the lever, at the same time pressing the button, current flows from the dry cells through the bare wire, through the relay into the ground, thence through the hoist-cable back to the cells. The current flowing through the relay closes a separate electrical circuit, which rings the signal-bell. The current for the bell-circuit is supplied by 30 dry cells in the hoist-room, but connection could be made with a direct power or lighting circuit.

The important feature of this arrangement is that the dry cells, placed on the cage, give a low-voltage current, only 10 or 12 volts, eliminating all possibility of danger, such as would be present were higher voltage used. Also, if the contact-lever should be accidentally struck and contact made with the bare wire, the circuit would not be completed, because in order to close it the button must be pushed at the same time the lever is thrown. The use of the relay in the hoist-room is also important, because it permits the use of a low-voltage current in the shaft and a higher voltage to ring the bell. In order to stop the hoist from the cage by the same wiring system, it is only necessary to place in the control circuit of the hoist another relay so arranged that when the circuit is completed in the shaft, this relay will open the hoist-control circuit. As soon as this circuit is open the no-voltage release on the hoist switchboard will be operated, cutting off the power and automatically stopping the hoist.

O. N. Friendly, general superintendent of the Judge Mining & Smelting Co., is installing a modification of the Eagle and Blue Bell system for use in the Daly-West shaft at Park City. It is planned to do all the signaling from the cage and have no signal arrangement on the levels except the flash or buzzer system for calling the cage. A number '0' bare wire will be suspended in the shaft with insulators every four feet. Instead of a hand-lever to make contact against the wire, there will be a continuous contact with the wire as between an electric motor and trolley wire. Six dry cells will be placed on the cage as at the Eagle and Blue Bell shaft, and the relays and bell circuits on the surface will also be the same; push-buttons will be used to close the circuit.

Double-deck cages are in use, and to make it possible for a cage-tender to give signals from the cage, while standing on the station at either side of the shaft, four push-buttons will be used, two on each side of each deck. By this method there is no possibility of anyone signaling the hoisting engineer except from the cage. It not infrequently happens that careless or ignorant employees signal the engineer when they do not know where the cage is, causing the engineer to move the cage when it should not be moved.

Systematizing Large Mine Examinations

By MORTON WEBBER

Engineers usually experience lack of confidence in themselves when entrusted with their first large mine examination. Their experience has been gained from the examination of small properties and prospects. The obtaining of the data in such cases is relatively simple and the work is done personally by themselves. The time allowed for large examinations is seldom proportional to the time obtainable for small jobs. For the latter 30 to 60 days are frequently afforded. After the completion of the examination a cash payment is seldom required. In the examination of a large and supposedly valuable mine 60 or 90 days are usual periods for examination when a large initial payment is involved. To obtain the necessary data in the limited time afforded, the engineer therefore must employ a sampling crew, a surveyor, and draftsmen, and he will probably have to arrange to furnish a composite sample that is representative of the ore of the mine for a metallurgical test. This procedure is becoming increasingly common because frequently large deals involve new treatment plants. The valuing engineer should also furnish an opinion on what changes, if any, should be expected in the composition of the gangue and metallic minerals in depth.

Since the ore for the metallurgical test is procurable only from developed openings and since the contemplated plant must successfully treat ore beyond these exposures after the present ore-reserves are consumed, and for other reasons connected with a competent examination, it may be necessary to call in a geologist as a consultant. In that case it is particularly necessary for the engineer to have a thorough grasp of the principles of mine valuation to enable him to present questions to the geologist vital to the appraisal of the particular mine. Otherwise he will get a mass of geological data a great proportion of which is of small economic value; for few geologists are mine-valuers. If the engineer has therefore the experience, or natural aptitude, to determine what are the economic geological questions governing a particular case, although he may not have the geological training to answer them, and can focus the geological consultant on these features, he will save considerable time in separating essential from non-essential geological information.*

It is therefore axiomatic that the engineer whose ex-

perience has been confined to the examination of small mines and prospects will feel nonplussed and timid when attempting his first large examination. There will be the unfortunate feeling of not knowing how to go about it, or where to start. Experience gained from comfortably cutting about 150 samples and submitting a report in 30 to 60 days will not help much when tackling a large operating mine involving anything from 10 to 100 miles of workings, masses of past-production records, a roomfull of maps with which the engineer is unfamiliar but which must be grasped in short order, and the necessity of cutting from 10 to 50 tons of samples and producing a composite sample for a treatment test, the whole job to be finished in about 70 days, for in a 90-day option the investing clients must have time to 'turn round' after receiving the report.

I shall endeavor therefore to recite some of my methods in systematically arranging the examination of a large mine so that the report may be submitted within the allotted time. I will use a large silver mine for an example, as its examination was typical of the various points that confront the engineer when examining a large mine that has come on the market.

The vendors claimed three things: (1) The existence of an ore-reserve of 300,000 tons, which, based upon an operating cost of \$7 per ton, represented an operating net profit of \$1,000,000. (2) That owing to the past life of the mine being through years of lower silver prices, large areas of old workings can be mined at a profit. That for the same reason a large number of stope-fills can be drawn profitably and treated. (3) That the present mine bottom is hopeful, the grade of the lowest level being as good if not better than the levels above, and that the shoots are equally long. That other successful mines in the district are mining profitably 900 ft. below the present bottom of the mine under examination.

The intending vendee accepted the above statements as the basis for an option. He, however, believed that the mill was old-fashioned, that by modern plant a saving in operating costs and additional extraction could be made of \$5 per ton or an additional profit of \$1,500,000 through plant improvement alone. In addition to this, a saving of another \$200,000 was hoped from improvement in mining methods. In the example under review stoping had been done by square sets and the preliminary examination, on which the above hopes were based, disclosed the possibility of employing shrinkage stoping with its obvious economies.

In the above example, and for that matter in all other examinations, the system I employ in procuring the data is similar. My methods may differ in degree but they do not alter. After I got over being frightened at the size

*This statement is not intended as uncomplimentary to the geologist. The training of the mine-valuer and the geologist is different. The valuer must think naturally along lines of finance, for mines are operated to make money. He must, however, understand geology sufficiently to appreciate the relation of geology to mine-valuation, for only thus can he ask intelligent questions of his less material brother, the consulting geologist. It is along these lines that teamwork between the engineer and geologist should be expected.

of the job I realized that the procuring of the data governing a large examination was as simple as obtaining the data for a smaller one. It is largely a question of doubling up the sampling crews and the number of trained assistants. The gulf the engineer has to cross is the step from doing most of the work himself to splitting the work up into departments under departmental heads.

A mistake the younger engineer is likely to make is to endeavor to get his sampling crew at work too soon. If he has brought a large crew to do the mechanical part of the sampling, the first impulse is to get them started. This is a mistake. The crew will get all the work they want before the examination is completed.

The first thing the engineer should do is to thoroughly familiarize himself with the mine he is reporting upon. For this reason it is preferable to detail an assistant to bring the crew a few days after his own arrival. If this is not feasible, as in the examination of mines abroad, where it is necessary to take the entire force *en bloc*, under no circumstances let the fact that your crew is hanging around for the first few days disturb you. The first thing is to thoroughly 'understand your mine'. This is best accomplished by investigating the workings and plant accompanied by the mine manager or some other person of technical training able to discuss the engineering features intelligently. If you want to make headway, do not treat him with suspicion. Treat him as you would like to be treated were you in his place. Because he is the engineer of the vendor it does not preclude him from being as honorable as you are. If you are just beginning to get the confidence of important capital interests (for this article is intended for the benefit of the junior engineer attempting his first big job), you may have some peculiar and unfortunate points of view. Some years ago I made a joint examination with another engineer who in his attitude toward the staff of the vendor showed himself to be a first-class snob and the friendly progress of our work was much impaired.

After a grasp of the physical situation is obtained, an investigation of the maps and records should be made. I was employed to report on a large operating mine in Canada that was under option to purchase. The vendee was a near-by mining company. I made arrangements to get my crew from the latter mine. They were to be forwarded on telegraphic instructions. By investigating the vendor's assay-maps I was able to prove on the basis of his own figures that the purchase price was unreasonable. In this manner the expense of a large sampling job was avoided.

After a thorough study of the property prior to sampling, the process previously referred to as getting to 'understand your mine', two important features should present themselves. The first is that the future life of the mine will depend on definite areas of ground, which, for simplicity, may be termed the prolongation of the deposit. This should not be confused with the ore-reserves, because their investigation is relatively simple. I refer to areas on which will depend the future life of the enterprise. Mines are seldom of interest to a purchaser for

their ore-reserves alone. There is little profit nowadays in buying ore, because developed mines that are for sale are becoming increasingly scarce. The purchaser must hope to make the major profit during the future life of the property as the outcome of greater skill in intensive development, the profit to be gained by spreading overhead and standing charges over enlarged operations, and the economies and increased extraction obtainable from a modern plant. The future life will depend on the extension of profitable ore with depth, or the extension of the mine in length, or additional life expected from later discoveries of parallel veins that may rejuvenate the entire operation.

Accordingly it is my practice to start on this part of the sampling early; that is, to commence on areas vital to the consideration of the future life of the mine. In the particular examination under review the sampling was commenced on the lowest level. As stated, the adjoining mines were operating profitably at greater depth. It could be determined at an early stage whether or not this mine had an attractive future life. Assuming the sampling of the mine bottom showed up badly, a basal step would have been made in the examination. The engineer would know that the mine was of value only in respect to its established ore-reserves.†

If the engineer is familiar with the terms of the deal, as he should be, he can then judge whether or not, under the terms of the option, it is advisable to proceed with the remainder of the examination. Accepting the owner's figures of the ore-reserves as a basis for calculation, their value to the proposed buyer will become a banking question of risk and interest. A price has to be paid for the ore-reserves, as a present value, and the proceeds of their marketing will become interest-earning over a period depending on their rate of consumption. The 'yardstick' is Inwood's tables coupled with a knowledge of the metal market. If the sampling of the prolongation of the orebodies is disappointing the engineer should notify his client. This will permit him to demand a radical modification in the purchase price or to terminate further examination expense. There is usually little incentive in the purchase of ore-reserves unless accompanied by future possibilities and the benefits of enlarged operations.

The second phase that will present itself as the process of getting to 'understand your mine' is that large areas may or may not contain ore. I do not mean the ore-reserves or their immediate extension. The majority of mines offered for sale have been insufficiently sampled. There are usually extensive workings that are supposed to contain low-grade ore or where new shoots are supposed to be coming in. In a general way, these areas are part of the future possibilities and they excite cupidity. They are usually so extensive in area and their value so

†Attention is particularly called to this phase, for developed mines with important ore-reserves frequently come on the market because the more recent development of the property by the owner has disclosed the limited life of the mine. In such cases the owner hopes that the ore-reserves will 'carry the sale' and that the finite life of the enterprise will be unapparent to the buyer. 'Caveat emptor'.

problematical that to sample at a close interval similar to that used in the estimation of the ore-reserves would entail considerable expense. My practice is to give these areas a preliminary sampling at a wide interval of about 30 ft. In this way much can usually be eliminated from further consideration and valuable areas indicated by the preliminary sampling can thereafter be sampled at a close interval to determine their width and value.

I have now dealt with the two main phases that will present themselves prior to commencing sampling and will assume that the engineer has a general grasp of the areas on which the future life of the mine will depend after the exhaustion of the present ore-reserves, and that he has decided to give certain extensive areas of possible, but quite indeterminate, value a preliminary sampling.

The time has now come to get the sampling crews to work. There is a fundamental feature in my sampling in that I personally decide on the position and length of the sample-cuts. I do not delegate this part of the work to an assistant. The essence of a mine examination is the understanding of the particular mine as exhibited in the placing and width of the cuts. A few cuts placed by an engineer of experience are worth a raft of samples poorly placed. I therefore always 'paint my own job'. This is done by whitewashing and numbering the strips to be later sampled by the crew. In this way each sample is my own. The accumulation of experience or heritage gained from sampling other mines is thus transmitted to the particular examination. The mechanical part, cutting uniform channels, quartering down and assaying, can be delegated to others.

The whitewashing of the sample-cuts is done by having tags of duplicate numbers strung on a wire. There are two adjoining tags, say, 256, next to these are two tags, say, 351, and so on. Numbers are not allowed to be strung in regular order for reasons that will be hereafter stated. In this way the strips to be channeled can be rapidly painted and numbered. Adjoining each strip of whitewash, or calsomine, duplicate numbers are affixed with a nail. When the members of the sampling crew draw the sample they take down one of the tags and place it in the sack with the sample. The other tag is left on the nail. This affords permanent identification of the cut and prevents confusion of the samples, it also enables the surveyor to plat the cuts with their width on the map. In this way the sampling part of the examination is conducted in three successive operations. First, the engineer with paint-pot, nails, and tags, accompanied by an assistant who notes the width of the proposed cuts; second, the sampling crew acting under a boss who cuts a uniform channel for the entire length of the painted strip, and third, the surveyor who plats the position of the cuts and checks the width and uniformity of the channeling. This phase of the work is important. It is necessary to know that the men cut the entire width painted.

By the above method the examining engineer can keep a mine 'painted' far in advance of the sampling crew. An active man can paint enough in one day to keep three

crews channeling for a week. In this way he can get his men all busy at underground sampling, commencing, as advocated, on the portions of the mine critical to the life extension of the enterprise. Thereafter he can devote his attention to the other phases of the examination.

In my practice the next step is inaugurating the department of mixing and quartering the samples to duplicate pulps. As this phase does not receive attention until the underground crews are at work, it is advisable to have an excess of sacks. This will allow the sampling crews to proceed without interruption during the training of the mixing-crew. After the mixing-department becomes efficient the excess of filled sacks can be worked off. The proportion of men cutting samples to those mixing will vary with every mine. The accessibility of the faces to be channeled, the amount of staging required to sample the backs of stopes, the sampling of raises and the hardness of the rock, make it impossible to suggest a standard proportion beyond that for every man in the mixing department, assuming it is intended to cut down to duplicate assay-pulps of 100 mesh, three samplers should be underground. This is merely a ratio on which to commence sampling. Adjustments should be made thereafter.

I will not describe the method of reducing samples to duplicate pulps, as this is standard practice. In respect to this part of the work, however, I may suggest that engineers frequently endeavor to reduce samples to pulp too quickly. I recommend a thorough mixing on a mat prior to cutting down. If this is done it will avoid a multitude of sins thereafter, for if a sample is once thoroughly mixed it can stand some careless treatment. If a sample is quartered with insufficient mixing and the opposite quarters are \$5 and \$7 per ton, and \$6 and \$8 per ton, respectively, it does not matter how much care is introduced thereafter, the error of 50 cents per ton at the start cannot be eradicated. For this reason I insist on all samples being mixed on a mat for not less than five minutes, depending on the ore. A clock is placed in the mixing-room so that the minimum mixing-time will be afforded.

After sampling is under way and likewise the reduction of samples, which should always be done on the surface, the next step is the map-work. In the case of large mines, where extensive maps are in existence, it is usually unnecessary to survey the entire mine. It is my practice to survey certain important portions of the workings and if the maps are found correct in these particulars to accept the remainder. On these maps I propound my own maps and make additional sections. It is generally necessary to compile different forms of maps to present the case clearly to my clients. Maps are the language of the engineer and this language should be clear and concise. Generally the maps of an operating property are sufficiently clear to the resident staff, as they are familiar with the mine. They are frequently insufficiently clear to a third party at a distance. I recently examined a mine where a plan showed that the workings curved like a bow. The sampling was shown on a longitudinal pro-

jection. One-half of the projection was foreshortened 60° and the remainder was foreshortened 25°. Such a sample map was misleading to even a trained engineer.

In the silver-mine examination the sampling of the stope-fills and the assembling of a composite sample for a metallurgical test was obtained at this stage of the examination, that is, after the sampling and drafting were safely underway. Had I desired to consult a geologist I would have engaged his services at about this time, as my work had progressed sufficiently to give me a thorough understanding of the mine and I would be able therefore to consult him on the particular points concerning which I wished to be advised.

In respect to the sampling of the fills, these were divided into two classes. Class 1, fills where there was good reason to believe their content could be treated with profit. Class 2, fills of more uncertainty. Small quantities were drawn from various stopes and placed in railroad cars and sent to a smelter for treatment. The object in dividing the fills into two classes and shipping separate portions was to prevent Class 2 from vitiating Class 1.

The method I employ of obtaining a bulk-sample for a treatment test depends on the size of the sample required. If a mill-test sample of 20 tons or upward is wanted, it is not procured until the mine is sampled. After the sampling-maps are completed it is feasible to shoot down portions of ore throughout the mine to furnish a composite sample representative of the average ore of the mine as disclosed by hand-sampling. This sample should be obtained on a foot-weight basis. That is, before making up the composite sample a foot-weight is determined upon, say for example, 50 lb. per sampled foot. If a mine has ten stopes, each stope will contribute its proportional foot-weight based upon sample-widths. If stope 'A' has 200 ft. of sampling it would supply two tons to the composite. If stope 'B' had 400 ft. of sampling it would supply four tons, and so on. In a ten-stope mine there would be ten components of the composite sample. The contribution from each stope is obtained by rows of 'pop-shots' uniformly spaced along the sample-cuts. In a large stope it is not feasible to pop-shot all the sample-cuts. In such a case it is my practice to shoot down a selected number of cuts that appear to represent the average material of the stope; and also to ascertain that the foot-dollar of the selected number is approximately similar to the foot-dollar of the total stope-sampling.

It is advisable to break down more than the foot-weight required from a stope rather than less. The excess above the stope foot-weight can be removed by cone-mixing. If too little is shot down the deficiency has to be obtained by removing more ore from the stope. This will introduce the personal equation which should be avoided after a method of sampling is determined upon. The assembling of the ten units or components of the composite sample so that the testing-plant will get the consignment as thoroughly mixed as possible is obtained by arranging the components in a circle and heap-mixing in the centre.

If a small test is required, 100 to 500 lb. for preliminary flotation tests, the sample is obtained from the rejects of the hand-sampling. The rejects should be stacked under original numbers. This is essential, for in the great majority of even profitable mines a large number of hand-samples will not come from ore-shoots and will therefore have no bearing on the case. By retaining all rejects until after the sampling has been platted and the average metal content of the mine determined it is possible to make up a composite sample representative of the profitable ore.

As stated heretofore, I avoid tagging the sample-cuts in consecutive order. This is to permit me to introduce the 'key series' of checking the sampling. This method was described in an article entitled 'The Detection of Salting', in the 'Mining and Scientific Press' of November 8, 1919. The method depends on removing a number of tags from various portions of the mine after the samples have been drawn and substituting new numbers. Instructions are then given to an assistant to have the original cuts re-channelled. The key of the old and new numbers is kept on my person. I do not expect the assays of each sample to agree closely each to each, but unless salting has been attempted or the cutting and assaying has been inefficient the averages should agree.

It is my practice to introduce two systems of key-series, one underground and the other by substituting the numbers of a series of pulps and having them re-assayed. The checking of a custom assayer is done by forwarding for assay two or more series of duplicate pulps masquerading under new numbers. It is obvious that if the sample-cuts were tagged consecutively the merit of the key-series, in that the examining engineer alone knows the key, would be lost.

The other phases of a large examination not discussed are the investigation of the title and the audit of the books. These duties may be placed on the shoulders of the examining engineer. Assuming that it is the engineer's duty to have this work done as part of the examination, as for example, in the case of an American engineer examining a mine in Colorado for a London company, the following procedure is suggested: The audit should be made when possible by a chartered accountant. Other accountants may be good and many of them are highly competent, but there is a security in the hallmark of the chartered accountant. Similarly a corporation attorney should be employed for the investigation of the title. In event of an engineer examining a mine in a community with which he is unfamiliar, and having the additional burden of passing on the earnings, financial state, and validity of the title, I recommend that he call upon a reputable bank in the neighborhood. He can thus get in touch with a responsible and competent attorney and accountant. Under no circumstances should he allow the vendor, his associates, or any person directly or indirectly connected with the sale to suggest whom to employ.

As the search of titles and the audit of the books cause considerable expense, it is suggested that this work

should be delayed until the engineer has a fairly good idea whether or not he will recommend the mine. He should not delay until rendering his report, for when the vendee decides whether or not he will proceed with the purchase the engineer's report, the audit, and the report on the title should be before him simultaneously. A better example of a tripod cannot be imagined. The audit may show the company in debt. The title examination may show that the corporation does not own the property. The engineer's report may show that the mine is bottomed. If one leg fails to stand up the other two will collapse. On the other hand, as suggested, the engineer should delay the examination of the title and the audit until he has reason to believe his report will be favorable. It is a waste of a client's money to pass on the title and audit the books of a mine that the engineer knows his client will not want.

Exploitation of Manganese Deposits

In the past, the steel industry of the United States has depended almost wholly on imports for its supplies of manganese. Many of the important domestic sources yield ores that in their natural condition contain less manganese than the foreign ores the steel industry has been accustomed to use. To make these domestic ores available, therefore, they must be concentrated or practice in the steel industry must be modified. Roughly, 25,000 tons of high-grade manganese ore is used annually for dry batteries, for chemical purposes, and in other minor ways, and approximately 750,000 tons is required for making steel. By present practice every ton of steel takes an average of about 15 lb. of metallic manganese, which generally is added to the steel in the form of an alloy. The standard alloys are 80% ferro-manganese and 20% spiegeleisen.

On account of the irregularity of manganese deposits and the uncertainty of an adequate supply of ore, great care should be exercised in connection with the various operations, particularly with respect to prospecting and mining. Similarly, preparatory to the erection of a washing or concentrating plant, the factors that have to do with the success of the work must be carefully considered.

In general, as regards concentration methods, manganese ores may be divided into two groups, as follows: (1) Ores permitting mechanical separation of the manganese minerals and the gangue, and (2) ores in which the manganese minerals and the gangue are so intimately associated that separation requires some hydrometallurgical or pyrometallurgical process. Heretofore, attention has been confined almost wholly to mechanical separation, chiefly by gravity.

The principal considerations affecting the cleaning of ores are:

1. The character and grade of ore.
2. The recoverable percentage of mineral.
3. Relative value of crude to cleaned ore.

4. Basis upon which royalty is paid, whether crude ore or the cleaned product.

Aside from the clay and other materials more or less intimately mixed with manganese, considerable silica is associated with the ores. The silica may be 'free' or 'attached'. The free silica can be readily removed by washing, but the attached silica, being embedded in the ore or attached to it can be separated, if at all, with difficulty.

High-grade ores, particularly when occurring in large masses, and soft ore, as pyrolusite, should receive the minimum preparation consistent with proper cleaning. Low-grade ores usually require much more careful treatment than the high-grade ores, and the work and expense of concentration depend largely upon the impurities present. Free silica is not difficult to separate from the manganese. Soft ore, or 'wad', although of high grade, is difficult to clean without great loss from fine, particularly when much fine sand is mixed with the clay and ore.

The recoverable percentage of mineral in the wash-dirt depends largely upon the character of the mineral. Certain clays are readily broken and separated from the manganese, whereas others become pasty when washed, adhering tenaciously to the particles of mineral. As a rule, the larger the pieces of ore and the higher the grade the more readily is separation from the waste effected, owing probably to the smoother surfaces. Nodular ore of small and fairly uniform size is readily washed and jigged, but fragments from large masses and rough particles resulting from decay of limestone and possible incomplete solution of manganese are difficult to clean.

The relative value of crude ore as compared with that of cleaned ore may be the deciding factor in determining whether a concentrating plant should be erected. During the past year a considerable quantity of low-grade ore was shipped at a low price, simply because there was a market for it. The question is whether such ore could not have been raised in grade by concentration, so as to have brought a price that would have warranted the erection of a suitable plant. However, uncertainty as to the extent of the deposits and the length of time the prevailing schedule of prices would be maintained did not foster experiments of this sort.

The grade of ore upon which royalties are assessed has been the cause of considerable trouble in different districts, but in most of the districts during the past year royalties were paid on all ores coming within the schedule unless otherwise specified. In the future high-grade ores will alone be subject to royalty charges. Moreover, careful mining in well-proved deposits of high-grade ore will be necessary in the various manganese districts. The ores mined will, in turn, require either close hand-picking or concentration in well-designed plants in order to produce a high-grade ore, low in silica and phosphorus. With a dependable output of such ore, it should be possible to continue operation in the face of foreign competition wherever freight rates to consuming furnaces are reasonably favorable.—U. S. Bureau of Mines.

Flotation Mill-Runs v. Laboratory Tests

By FREDERICK G. MOSES

INTRODUCTION. At the present time a flotation plant is rarely built until the ore to be treated has been tested thoroughly in the laboratory and a flow-sheet carefully prepared. It is the object of the laboratory tests to determine all the small factors that may have a bearing on the operation of the larger plants. Within certain limits this can be done successfully and there are few finished mills that cannot be made to duplicate closely the results obtained in the laboratory. However, it must be borne in mind that in the mill it is sometimes necessary to do things that are not required in the laboratory in order to obtain the same results. It is usually a good plan to assume that success in the laboratory simply means that there are a certain set of conditions under which large-scale results can be obtained and that it will be necessary in the operating plant to duplicate these conditions in whatever way may be required, before comparable results are possible. This fact brings in a consideration that has often been overlooked. In the laboratory much of the work is done in order to determine the exact kind and quantities of flotation oils that will give the best results. It has been found, however, that the same oils that have given the best results in the laboratory may not give the same results when used in the mill. There are several reasons for this. They may be segregated under the heads of grinding, manipulation, water, and time of treatment.

MILL AND LABORATORY GRINDING. There is no doubt but that the grinding that can be carried out in the laboratory and in the operating mill is different, and this difference is bound to have an affect on the results obtained. The different effects of grinding on flotation oils may be caused by any one of several factors, among the most important of which may be mentioned the difference due to grinding in batches, which is necessary in a laboratory, and continuous grinding, such as is done in the mill. This batch-grinding necessitates the use of the same water during the full grinding period, while in the large grinding machines the water continually changes to a varying extent. These two sets of conditions have decided effects on the action of the oils, particularly when the oils are added in the grinding machines.

It is difficult to name all the ways in which grinding may affect flotation oils, largely because we understand so little of the true action of the oils. One factor is the difference in temperature. Practically all flotation oils are more or less volatile and if the commercial machine operates at a higher or lower temperature than the laboratory machine, the results will differ. One experience of this kind that may be cited happened at Superior, Arizona. A large Hardinge mill was being operated at full capacity. It became necessary to reduce the tonnage in the mill, owing to lack of ore. It was found that when

the smaller tonnage was being ground in the mill, the flotation results were quite different from those obtained when the larger tonnage was being ground. Various explanations were considered but the conclusion reached was that while operating on a small tonnage the pulp in the mill became excessively hot and volatilized some of the lighter constituents of the oil.

MANIPULATION. Another cause of variation in results may also be the different ways of handling the pulp in the laboratory and in the mill, or differences in manipulation, necessitated by the different conditions. When a mechanical machine is used in the laboratory and the oil is dropped directly into the pulp, we have a certain condition. The machine is operated until the oil is thoroughly distributed in the pulp, then speeded up and the froth taken off. Of course, this manipulation is different from that of the continuously operated machine and different results may be obtained even with the same reagents.

DIFFERENCE IN WATER. Undoubtedly one of the greatest causes for varying results is the different water used. There is no question but what the physical and chemical characteristics of the water have decided effects on flotation results. Therefore, the same water should be used in the laboratory testing as will be used in the mill.

EFFECT OF TIME. Another factor that may cause a discrepancy is variation in the time of treatment. In the laboratory it is common to treat the ore as long as may be necessary to get a satisfactory extraction. This may require from 45 minutes to one hour and may necessitate adding small quantities of oil every few minutes. In the large mill the time of treatment can, of course, be varied, but the limits will be comparatively narrow. If the mill is so designed as to treat the ore for 45 minutes, an oil that would give satisfactory results in an hour in the laboratory could not be expected to give satisfactory results in the mill. If the ore can be treated only 45 minutes conveniently in the commercial plant, it is necessary to use an oil that will give the desired extraction within that period. It may be found that to do this requires an oil entirely different from that which has given satisfactory results in the laboratory.

DESIRABILITY OF MILL-TEST OF FLOTATION OILS. These things have been mentioned to emphasize the necessity for continuing the testing of various flotation oils even if the mill has been built and is in successful operation. It has been found that many operators are prone to take it for granted that the oils they are using, or that they were advised to use by the testing laboratory, are the ones best suited for their purpose. This is seldom true; a small amount of experimental work in one unit of the mill will often give results that are much better than those already obtained and will more than pay for any extra trouble involved. Such experimental work will require extra labor and the purchase of additional oils for testing. The work may also result in the loss of the oils that may be proved less satisfactory but this loss is a comparatively small item, if the investigation proves that some other oil will give better metallurgical results.

The Yellow Pine Mine at Goodsprings, Nevada

Special Correspondence

The Goodsprings mining district is situated in Clark county, Nevada, about eight miles west of Jean, a station on the Salt Lake Route. The principal ores at Goodsprings are oxidized lead-zinc and copper-gold, some of the latter containing platinum-bearing minerals. The

1915. Before 1913 work was done through a 300-ft. inclined shaft. Square-sets are used in the stopes, this method replacing a combination of the caving and shrinkage systems used prior to 1912. To assure a clean product, stoping is done with single-jacks. Forty men are employed on one shift and three machine-drills are used in development work. The output is 1600 tons per month. The surface equipment consists of a Fairbanks-Morse semi-Diesel engine operating a Fulton hoist, Ingersoll-Rand air-compressor, and a generator to furnish electric light and power for the mine, and power for a Blake crusher. A Chicago pneumatic direct-driven air-compressor is used as an auxiliary.

The mill was com-

GOODSPRINGS, NEVADA

lead-zinc ore has a high silver content. The ore occurs near, and in places in contact with, large monzonite-porphry intrusions. The contacts are conformable with limestone strata dipping 35°. The deposits are replacements, apparently confined to the limestone exclusively. The Yellow Pine is the largest producer in the district and since 1912 the company has paid \$3,030,000 in dividends. The mine is 4½ miles north-west of the

town of Goodsprings and the mill is in the town. The mine, mill, and town of Jean are connected by a narrow-gauge railroad built by the company in 1911.

The mine-shaft is 950 ft. deep on an incline of 35°. Hoisting is done with a two-ton skip at an average rate of 20 tons per hour from the 300, 500, 700, 800, and 900-ft. levels, where there are large skip-pockets. The shaft now in use was started in 1913 and was completed in

THE YELLOW PINE MILL

pletely reconstructed and remodeled last year. The machinery, driven by a 100-hp. Fairbanks-Morse semi-Diesel engine, consists of rolls, jigs, and 6 Deister-Overstrom concentrating tables. The coarse crushing is done at the mine. The lead-silver concentrate is shipped and the zinc concentrate is calcined. The calciner, which was recently completed, treats the zinc produce by driving off the moisture and a large proportion of carbon dioxide, thus

reducing the weight and giving a material saving in freight charges. The United States Bureau of Mines is experimenting with a process to drive off by chloride volatilization fumes containing lead and silver. The fumes would be collected in a Cottrell precipitator. The perfection of this process would be of importance to the entire district.

The district comprises 400 square miles at the southern end of the Spring Mountain range. With the exception of the Yellow Pine, practically all mining is done near the surface, but some of the other companies have made remarkable production for the amount of work done.

MAP OF SOUTH-EASTERN NEVADA

The Boss mine is interesting as a considerable producer of copper and also as a producer of platinum, palladium, iridium, and gold. Other mines in the district that are or have been producers are the Alice, owned by the Yellow Pine Extension; Goodsprings Bill Nye, Sultan, Christmas Consolidated, Anchor, Bullion, Ingomar, Milford, Prairie Flower, Red Streak, Azurite, Annex, Copper Sides, Mobile, Whale, Oro Amigo, Potosi, Monte Cristo, Root Zinc, Copper Peak, Contact, Dawn, Singer, Tam O'Shanter, Green Monster, and the 20 patented claims of the Campbell estate.

UNDER the appropriation of \$75,000 made for the investigation of the mineral resources of Alaska, the U. S. Geological Survey has dispatched seven field parties to the Territory. The work to be done is that of extending the surveys and investigations which were begun in 1898.

Osmiridium in Tasmania

The mining of the rare mineral osmiridium in Tasmania is attracting widespread attention, and it is said that the island promises to be the world's chief producer for some time to come.

For months past the Tasmanian Mines Department has been investigating the osmiridium fields of the west coast. The work includes a complete geological survey of the various fields in which osmiridium occurs, from Nineteen Mile creek in the north to Wilson river in the south, and the nature of the deposits and the distribution of this precious metal, which is now worth about \$195 per ounce, has been carefully investigated. The publication of the complete bulletin is expected to throw much light on the subject. It was not until 1910 that the Department officially took notice of osmiridium among its mineral resources, and then efforts were made to ascertain values and outputs. These have since been carefully placed on record, thus enabling the State to enter the world's markets and attract attention to its new and promising source of mineral wealth. The Department ascertained in 1910 that 120 oz. had been produced in that year, and by its assistance the output in the following year was more than doubled. In 1912 the output rose to 778 oz., and in 1913 it was 1261 oz. This figure would have been far surpassed in 1914, it is stated, but for the War, and actually stood at 1018 oz. in spite of the check the industry received. Under the influence of the War for the next three years the output was 247, 222, and 332 oz., respectively. As osmiridium was a precious metal requisite for munitions of war, manufacturers, finding their usual sources of supply cut off, turned their attention to Tasmania. This resulted in keen buying, which sent the output up to 1606 oz. in 1918. With the close of the War the rush collapsed, and for the first quarter of 1919 only 209 oz. was produced, but more stable conditions set in and the production for the year reached the record total of 1669½ ounces.

The Tasmanian Mines Department recently published an interesting bulletin on osmiridium mining in Tasmania, prepared by Campbell Brown, who personally investigated the fields. According to this bulletin, the precious metal is found in various districts in the west of Tasmania, all of them more or less remote and somewhat distant from each other, yet bound together by a common invariable feature, namely, the occurrence in the neighborhood of great masses of serpentine rock. On the brow of Bald Head, in the Savage River district, facing Nineteen Mile creek, there is an osmiridium mine which is quite unique. Here a well-known miner, according to the official bulletin, has been quarrying solid serpentine rock for over six years and, by crushing it, obtaining high-grade metal. He is the first and only miner in the world, so it is officially noted, to find the precious metal actually occurring in the solid rock.

THE principal use of zinc oxide is in the manufacture of rubber products, chiefly automobile tires.

First-Aid and Mine-Rescue Contest

By F. J. BAILEY

The event of the year, as far as the million miners of the United States are concerned, is the International First-Aid and Mine-Rescue Contest that will be held on September 9, 10, and 11 at Denver, Colorado, under the auspices of the Bureau of Mines.

The contest will be open to all first-aid and mine-rescue teams connected with the mining and metallurgical companies of the United States, Canada, and Mexico. Prizes of gold medals, cups, and banners will be awarded to the teams most proficient in the art of saving human life. A number of similar contests have been held in the past by the Bureau and each succeeding contest has aroused increasing enthusiasm among the mining fraternity.

A little more than ten years ago the Bureau of Mines, under the late Joseph A. Holmes, its first director, introduced into the mines a new method of life-saving, namely, the use of oxygen apparatus, which permits trained rescuers to enter a mine filled with poisonous gases that would kill in an instant. That allowed the formation of mine-rescue crews at the mines, and today there is not an important mining community that does not boast an expert crew of life-savers. With the trained rescue miner, wearing the oxygen apparatus, has come the trained first-aid man who takes the victim of a mine disaster and gives him the emergency aid that may save his life or prevent him from becoming permanently crippled.

Today there are more than 100,000 men in this country trained by the Bureau of Mines in modern first-aid or mine-rescue work, or both, all of them volunteers, ready to help their own or those in some other place, no matter

RESCUER EQUIPPED WITH OXYGEN APPARATUS

FIRST-AID TEAM FROM BUTTE IN COMPETITION AT PITTSBURGH

where. The Bureau maintains ten fully equipped mine-rescue cars with trained crews that visit as many mines throughout the country as they can, training men in modern life-saving, and now and then stopping their work to rush to a disaster and assist in a practical way in the saving of men from death. The Bureau also maintains ten stations and five trucks that perform similar duties. In this work altogether the Bureau employs 50 trained men.

The mining industry in this country employs more than a million men, and more than 3000 are killed each year while at work. This life-saving work has now been in existence ten years or more, and the records of fatalities show that in that time the lives of 5000 men have been saved. To state this in another way, had the fatalities been in the same proportion during the last ten years as in the preceding ten years 5000 more miners would have lost their lives.

There is such interest in these contests that teams have been busy all the summer in local and State contests preparing by competition for the big event. California, Kentucky, Alabama, Indiana, Oklahoma, Virginia, Iowa, and West Virginia have selected their best teams for the Denver meeting. The Lehigh Valley Safety Division of Pennsylvania recently held a 'No Accident' week and picked out the best teams in their localities to attend the contest in September.

Last year the contests of the Bureau were held at Pittsburgh, with 108 teams participating. This year the entries close on August 26, and must be filed with the Bureau at its Pittsburgh office. D. J. Parker, head of the rescue service, will have charge of the affair.

One of the spectacular events will be an actual demonstration of the utility of the aeroplane in rescue work in transporting engineers and oxygen apparatus to the scene of a disaster. While the rescue teams are showing their proficiency on the field where the contests are to be held, an alarm of a supposed mine disaster will be telegraphed or telephoned to the hangar of the nearest aeroplane of the U. S. Air Service. An aeroplane will be dispatched to pick up Bureau of Mines men and apparatus, bringing them to the field as quickly as possible.

Another feature of the meeting will be the formal presentation of gold medals to miners for deeds of bravery in saving life in the United States during the last three years. The awards will be made by Dr. Frederick G. Cottrell, Director of the Bureau of Mines, in behalf of the Joseph A. Holmes Safety Association, of which he is also president.

The Handling of Explosives

Explosives should be stored so that they will be in good condition for use, so that they will be available when desired, and in such quantities and in such locations as not to be a menace to life or property, says a recent bulletin by S. P. Howell, of the U. S. Bureau of Mines. Explosives will be in good condition if stored in dry well-ventilated magazines situated on well-drained ground.

They should be purchased in such quantities that they may be used without an undue period of storage, and the older explosives of any desired brand and grade should be used first. The temperature of the storage place should not exceed 90°F. and the magazine should be protected by adequate means. Security against premature explosion or burning is obtained if the magazine be of incombustible material; if the ground around the magazine be cleared of combustible debris; if blasting-caps and electric detonators be not stored in or near the magazine; if the ventilators be screened to prevent introduction of sparks; if no boxes are opened in or near the magazine; if its contents be protected from bullets by its location or construction of bullet-resisting materials.

Magazines should be situated with respect to uninhabited buildings, public roads, and public railroads, in accordance with the American Table of Distances. This table represents the judgment of experts and provides a material decrease in the distances at which magazines may be located from buildings, railroads, and roads, if they be barricaded.

Good practice in the transportation and storage of explosives presupposes conforming to the following:

- (1) Carry detonators and electric detonators, separated from explosives.
- (2) Make-up primers at or near the working place.
- (3) Keep electric detonators away from batteries, blasting machines, and other sources of electric current until immediately before blasting.
- (4) Carry and store explosives at such times and in such places that, should premature explosion occur, it will injure the least number of persons.
- (5) Keep explosives, fuse, detonators, and electric detonators away from open lights.
- (6) Keep black blasting-powder away from electric currents, and especially do not transport explosives in a motor unless they are enclosed in a non-conducting receptacle.

In the preparation of primers and the charging of holes, the following precautions should be observed:

- (1) Use a good quality of fuse and crimp it on the detonator with cap-crimpers that are in first-class working condition.
- (2) Imbed the detonator or electric detonator in the cartridge of explosive and secure it firmly in place so that it may not become separated from the explosive. If fuse be used with the detonator, it should not be imbedded in the cartridge, for side-spitting may ignite the explosive and the full energy of the explosive be not obtained. If an electric detonator be used, wire should not be looped in such a way as to invite a short circuit.
- (3) Put stemming in the drill-holes and tamp lightly if close to the explosive.
- (4) Use wooden tamping-sticks.
- (5) If firing is done electrically, connect the battery or blasting-machine after all other connections are made, and disconnect the battery immediately after firing or attempting to fire the shot.
- (6) Do not use short fuse.

The Engineer and National Prosperity

By GEORGE OTIS SMITH

*No profession can claim exemption from citizenship. The constitutional privileges of citizenship are also constitutional obligations, for democracy distributes broadcast duties as well as rights. The engineer cannot dodge his responsibility as a citizen unless he is a conscienceless slacker. Moreover, even a reconnaissance survey of the subject is enough to show that the engineer has the making of a good citizen.

The best American citizen is and always has been he who lives not for today so much as for tomorrow. The pioneer and the volunteer soldier alike choose hardship and danger that there may be a larger measure of comfort and safety in the future. Regard for the future is not only a good definition of civilization but it is a practical kind of simple test to apply to our every-day motives: Are you and I seeking an easy today or a safe tomorrow?

Now, as I understand the requirements of effective citizenship, the engineer measures up to the specifications: he is forward-looking, he seeks to safeguard the future, and he is constructive by training and habit.

Need I say much to convince you that while to look backward is a large part of the lawyer-statesman's code, to look forward is the professional habit of the engineer? Where could be found better evidence of the vision of the engineer than this city of Washington? Our first President was successively a civil engineer, a military engineer, and a nation-builder; and his vision of the America-to-be was so far-reaching that his contribution to city-planning has proved no less adequate than beautiful, even though since he selected this site for the new nation's capital the population of the United States has increased more than twenty-five fold. Washington the engineer planned for national prosperity and planned well.

The engineer of today also thinks in terms of the future, and because he ever keeps the factor of safety in mind as he works I have chosen to call him an insurance agent of the first magnitude. National prosperity will not satisfy us unless it is backed up with guaranties of permanence, and so it is that I appeal to the engineers to help write this nation-wide endowment policy to run to the benefit of our children's children. My political conviction is that the future of our nation will be largely what you engineers make it, and national prosperity must be worked out in terms of the nation's industry. The public questions of the day are largely matters of production and distribution, and however humanistic or idealistic or altruistic you and I may wish to be, the future of America can be safeguarded only as the plans are drawn up by citizens like you, who trust to the eternal

laws of matter and energy rather than to the broken reed of political expediency. This industrial nation needs citizens who will patiently lay solid foundations of fact and erect upon them structures of just action in which there is a factor of safety large enough to safeguard the nation's future prosperity.

The third link that connects the engineer and national prosperity is his constructive habit. It is not enough to know the truth; we have to translate it into action, and herein lies the distinction I draw between science and engineering: what science has discovered engineering must apply. Take this thought over into politics, and the peculiar usefulness of the engineer-citizen becomes almost self-evident. He has no use for the abstract except as the formula or the equation may affect his working plan. The engineering habit of mind is to trust implicitly the constants determined by science and tested by experience, but such faith is only the point of departure—works, not faith, is the engineer's creed, and it is his task in life to construct.

Now it is just this constructive tendency that we need more of in American politics. In political procedure we use practical engineering simply as a source of figures of speech—the terms 'log-rolling', and 'wire-pulling', 'steam roller', and 'side-tracking' are suggestive of the world of work, but only suggestive. In keeping our political institutions in running order, the legislative habit is to putty up any cracks in the structure that indicate weakness, without making any inspection of the foundations. And I regret to record my observation that in our legislatures, whether State or Federal, we find too little confidence in experts, possibly because the best of our scientists and engineers are rarely if ever seen or heard by those who control matters of statecraft. The skilful faker has had a standing here in Washington that he could not get in business circles. However, there has been some improvement in the status of the specialist, though even now a well-displayed sensational news item about a new motor fuel is likely to seem to the legislator a more acceptable basis for a Government investigation than a well-considered and therefore conservative statement by a chemical engineer of world-wide repute. Nor is the perpetual-motion variety of optimist without a hopeful following. Now it is this condition, this need of light, that demands a larger interest in politics on the part of our engineers, not so much through their great national organizations as in the capacity of individual citizens.

Our political temper today puts too much stress on legislation and too little on execution; we do not even reach the stage of a working plan. A new law is offered as the cure-all, whatever the evil that appears, and in devising the new law often the chief feature sought is

*A speech made at the Engineers Conference at Washington on June 3.

novelty; at least the remedy proposed must look new. The engineer's methods are different, both in planning his new structures and in putting them to use; to meet new requirements he usually adopts well-tested plans; he naturally seeks the safety of experience. And his structure once erected, his machinery installed, or his process perfected, he provides for its operation in accordance with his plans. This reliance upon well-tested facts of experience; this attention to the many details which taken together provide the requisite factor of safety, this 'seeing the thing through'; are all working habits that the engineer-trained citizen can well take over into his political life. As I read American history, I believe that the intensely practical yet altogether progressive leadership of George Washington in affairs of state was possible because he was thoroughly a man of affairs, an explorer and pioneer, a leader in experimental agriculture, an administrator of business, a promoter of inter-state waterways, and even a drainage engineer. The earliest precedent that we have here in America, then, is that an engineer makes the best type of President; but most of us can only aspire to be useful private citizens, and more useful if active in public affairs.

The constructive habit is sadly needed in these days of change. The critic is abroad in the land, and he attacks our institutions as the wrecker rather than as the builder. My own conception of political reconstruction is best illustrated by what we have all seen, the erection of a new railroad bridge. The bridge-engineer may well be taken as the type of worker we need in public life. You have seen how, with his plans prepared to the last rivet, he has replaced the small and inadequate and possibly weakened bridge with the larger and stronger and up-to-date structure, and he has done this without interruption to traffic. His plans provide for one essential that is lacking in too many Utopian schemes: the bridge workers build up faster than they tear down, and therefore there is always a bridge to use.

This nation of ours is a going concern; indeed, the rate of our progress is much more rapid than many of our statesmen realize. Changes must be made to meet the demands of the heavier traffic, new structures must be erected, new motive power must be provided, and the effective citizen of today is one who can see ahead of the present moment, who can plan to meet safely the demands of the future, and who has likewise the will to build the needed structures, without tearing down too rapidly the house of state in which we live. I believe the engineer is a citizen of just that type.

IMPORTS of sodium salts in 1919 amounted to 522,000 tons, valued at \$20,704,000, as compared with 2,111,000 tons, valued at \$90,939,000, in 1918. This great decrease in 1919 was caused almost entirely by a decrease in the imports of sodium nitrate, which is the sodium salt imported in largest quantity, the imports of all other compounds having actually increased in 1919 over those in 1918. The imports of sodium cyanide, sodium ferrocyanide, and sodium sulphide were notably greater.

Gilsonite

Among the natural hydrocarbons are gilsonite, elaterite, wurzilite, glance pitch, manjak, grahamite, albertite, and ozokerite. With the exception of ozokerite and other mineral waxes, they all more or less resemble asphalt in that they are dark brown or black bituminous substances of organic origin, generally with a resinous lustre.

Gilsonite or uintaite is an asphaltite characterized by a black color, conchoidal fracture, bright to fairly bright lustre, red-brown streak, specific gravity 1.01 to 1.10, hardness 2, and a melting point of 250° to 350°F. It is found only in the United States in a belt in the Uinta basin, about 65 miles long extending from Rio Blanco county, Colorado, into Uinta county, Utah, most of the important veins being in Utah. The veins are more or less parallel, having a general strike of north-west to south-east. They vary in thickness from a few inches up to 18 ft. and some are over 8 miles long. Branch veins joining the main veins at very acute angles are common. The walls, either of limestone or shale, are nearly vertical and are often so impregnated with gilsonite for several feet that no sharp line of demarcation exists. Close to the walls the gilsonite has the characteristic columnar structure perpendicular to the walls which is common to all asphaltites. Near the outcrop gilsonite loses its brilliant lustre and becomes a dull black through weathering. The methods of mining gilsonite are crude, little machinery being used. Little or no timbering is necessary, as the walls are usually strong and stand well. The ore is hoisted from underground, sorted, and packed in bags.

Two grades are marketed, 'selects' or 'firsts', and 'seconds'. Selects are taken from the centre of the vein and have a bright lustrous conchoidal fracture. Seconds come from near the walls and have a semi-conchoidal and semi-lustrous fracture. In 1918, 31,918 tons, valued at \$863,826, or an average of about \$27 per ton f.o.b. cars, was shipped from this district. Since the freight from the mines to the railroad averaged about \$10 the average price f.o.b. mines was about \$17 per ton. There were five producers in Utah in 1918. Gilsonite is used principally for the manufacture of paints, varnishes, and japons, and it is regarded by some as the most valuable hydrocarbon for this purpose. Unlike grahamite, gilsonite and glance pitch will mix in all proportions with fatty-acid pitches. Such mixtures are utilized for a great variety of purposes. Gilsonite is also used to a large extent in the rubber industry. Pure rubber is sensitive to heat and cold, but a vulcanized mixture of gilsonite and rubber has different physical and chemical properties and will resist both oxidation and changes in temperature. In such instances gilsonite may not be regarded as an adulterant but as a valuable constituent. Gilsonite also is used to some extent in prepared roofings and flooring materials, in paving cements; and, when mixed with other hydrocarbons, in pressed and molded insulation, electrical insulating tape, etc. Recent market quotations for gilsonite are reported at \$55 per ton, f.o.b. New York City.—U. S. Bureau of Mines.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

NEW PLANTS ARE UNDER CONSIDERATION

GLOBE-MIAMI.—It is reported that the International Smelting Co. is planning the erection of a large acid-plant. The purpose of this plant is to manufacture sulphuric acid from the smelter fume. Estimates are made that considerably more than 100 tons of sulphur is poured into the atmosphere each day in the form of sulphur dioxide. The acid-manufacturing plant will really be a by-product plant, as it will utilize a considerable quantity of this sulphur which is at present lost. The sulphuric acid produced will be used in the proposed new leaching-plants which will be constructed by the Inspiration Consolidated Copper Co. The mixed ores will be the first to receive acid treatment. At present only sulphide ores are being mined and treated by flotation; there is a high recovery of the sulphides and a low recovery of the oxides. The next metallurgical step will be to give the mixed ores the double treatment, first by flotation and then by leaching with acid solutions. After this practice has been fully developed, the next step will be the leaching (without flotation) of ores which contain oxides only.

The surplus acid will be shipped to a powder factory near Benson, Arizona, where it will be utilized in the manufacture of dynamite in a new plant at that place. It is reported that C. E. Mills, formerly general manager for the Inspiration Con. Copper Co., is president of the powder-manufacturing corporation, which, it is understood, is an association of the copper producers of Arizona, who will in the future manufacture the dynamite used in their mines from the sulphuric-acid output of their smelters.

A copper refinery in connection with the International smelter works is being considered also. This will avoid sending the pig-copper produced by the International company to Eastern refineries and the plant will probably also treat copper produced by neighboring smelters. If the proposed plans materialize, the copper consumer in the South-West will be saved something like 6000 miles of freight charges on the finished product, which under present conditions must be shipped to the Eastern seaboard to be refined and then returned to the consumers.

It is reported that the Grand Reef mine, in the Aravaipa district, in Graham county, about 60 miles north of Wilcox, has been purchased by the Aravaipa Leasing Co., which is controlled by the American Lead & Zinc company.

The last report of the general manager for the Magnia Chief Copper Co. to the stockholders is more favorable than former reports. Erection of heavy equipment is announced; also the fact that the engineers have reported available ores amounting to 250,000 tons. Doubling of the reserve within the next 90 days is predicted. Construction of a 100-ton flotation-plant is to start soon, the report says. Pending its erection the company plans to send 50 tons of ore daily to the Hayden smelter. Shipments of ores to the smelter have returned as high as 28% copper and 10 oz. silver per ton. As the ore comes from the mine it will average 9% copper and 6 oz. silver, with some gold.

BISBEE-WARREN.—The flow of water recently developed by the Copper Queen Con. Copper Co. in its Calumet & Cochise shaft, primarily for use in the new mill, now in course of construction, is sufficiently large to permit of a portion of it being used for irrigation purposes by the residents of Warren. This water is remarkably pure and clear and, coming from a tank high on the hill above the shaft, a high pressure is developed, which permits the use of revolving sprays for irrigation.

PATAGONIA.—A large body of copper ore is reported in the Wild Horse mine, situated near the 3-R mine, about seven or eight miles from Patagonia. Gray brothers, owners of the Wild Horse, have been in the district approximately 15 years and are enthusiastic over their find. H. J. Gray, senior member, was for 17 years superintendent of mines in the Tombstone district.

COLORADO

SILVERTON DISTRICT IS BOOMING.

CRIPPLE CREEK.—Production during July, as reported from the various reduction plants, totaled 38,222 tons; average value, \$12.10; gross bullion-value, \$464,568. The Golden Cycle mill at Colorado Springs treated 17,500 tons of ore averaging \$20; Independence mill of the Portland G. M. Co., at Victor, 20,022 tons of ore averaging \$3.10. There was shipped direct to smelters 700 tons averaging \$75 per ton. The Portland company paid a dividend of \$45,000 and the Golden Cycle one of \$30,000 during July.

Tests on Blue Flag ore at the plant of the Denver Engineering Works have proved satisfactory, and a flotation unit will be installed at the mill on Raven hill, to be running by the end of September. Equipment has been ordered. Development at the 1200 and 1400-ft. levels is reported to be encouraging both as to the quantity and grade of ore under development. The Blue Flag com-

pany owns property in the Patagonia mountains, Arizona, and following the recent development on the World's Fair group, immediately adjoining, the lease and option to purchase the Blue Flag group has been cancelled. The Arizona property is to be operated on company account. Important discoveries have been made on the north-west slope of Battle mountain by the Portland company, and by the Modoc Consolidated company on the south-east slope of Bull hill. The Portland discovery, made on the Wisconsin claims, at a depth of 1700 ft., is reported to be rich in gold. The Modoc find was made at 1300 ft. from the Last Dollar or No. 2 shaft. The orebody in places measures 40 ft. in width and is of good milling grade.

SILVERTON.—San Juan county is experiencing unprecedented activity; old mines are resuming and new companies, soundly financed, are starting. Production will be far in excess of last year and may reach a new high mark. The Sunnyside M. & M. Co. has in excess of 400 men on its mine and mill payroll, and a larger force would be employed at the Eureka property if miners were obtainable. The mill is running at close to capacity. The Gold King Extension company is operating three shifts at mine and mill and heavy shipments of concentrate are moving to the smelter at Leadville. High-grade mill-ore is being concentrated at the Iowa-Tiger mill in Arrastra gulch and bi-monthly shipments are made to the Southwestern Leasing Co., operating the property. The Astor, Copper Bell, Toltec, and Mable mines are in operation by the United States Mining Corporation and shipments, it is reported, will shortly be moving. The Gnome Mining Co., operating the Columbus at Animas Forks, is opening rich ore in the vein cut last fall; a milling plant is to be constructed.

Powerful mining machinery is being installed by the Silverton Mines Co. on its Bandora property in the South Mineral district, 8 miles south of Silverton. The Mazeppa mine in the same district will soon be shipping; a good grade of ore is now being developed. The Red Mountain Mines Co., operating the Yankee Girl and Genessee near the San Juan-Ouray boundary, is shipping to the Durango smelter and the Barstow is producing and shipping high-grade concentrate to the Durango plant.

TELLURIDE.—The Smuggler company has a large force employed clearing away debris from the Pandora fire in preparation for the new flotation plant. Mine and store buildings are nearing completion. Machinery for the plant is arriving. The Valley View Leasing Co. has its new mill at the Matterhorn in operation and with large reserves of milling-ore blocked out the plant will be operated at capacity following test runs.

ASPEN.—A gold-bearing vein has been opened by an irrigation ditch on the Clavel ranch, about eight miles from the city. Samples assayed gave results of 35 oz. gold from a 12-in. streak of ore. The owner will develop the prospect "when he has time", he says. Supplies have been sent up to the Turley tunnel on Montezuma mountain by Aspen parties who have financed the locator,

Henry Turley, who located a tunnel-site following the discovery of a vein of rich silver ore last fall. A mill-site has also been located. The property has good prospects.

MICHIGAN

MOHAWK.—WOLVERINE.—MAYFLOWER.

CALUMET.—Mohawk's operations, considering labor conditions, are continuing at a good rate and openings are on a par with those of a year ago. Production, however, is only about 50% of normal, but this is the general ratio that is maintained by most of the Lake Superior mines. In No. 5 shaft, on the 21st level, drifting is well under way in both directions. In No. 6, which also is sinking, the 17th level soon will be cut and drifting will be started. No. 4 shaft still is producing 'rock' that yields considerable over 24 lb. per ton on the 24th and 25th levels.

Mohawk is using stope-scrapers to advantage and arrangements are being made to install more of them in at least two shafts. At the same time experiments are being made with a 'zinc-field' scraper for use in the levels, and the miners are confident that the device will be a success. So far as is known, the only mines in which such a scraper is being used are the zinc properties, from which it derives its name. It is built so that it can draw the rock up an inclined level and drop it into the cars. If it fulfils predictions, it may go a long way toward attaining a goal that the whole Michigan copper region is seeking and the time when 11-lb. rock can be mined profitably may not be so far distant, as predicted recently by James MacNaughton, general manager for the Calumet & Hecla. Mohawk and Calumet & Hecla, to a certain extent, are working together in experiments with stope-scrapers and there is a likelihood that this device will be universally adopted for the C. & H. properties. Quincy also utilizes scrapers in its flat stopes and this method is usually successful.

Wolverine will not complete the repairs to its mill for another week or ten days. Production is not suffering, however, for a stamp-head in the Mohawk mill has been allotted to Wolverine. Meantime both No. 3 and 4 shafts are operating, but, like Mohawk, production is about 50% of the peak. As soon as North Kearsarge is able to take care of the flow of water that seeps from South Kearsarge through Wolverine ground, Wolverine will be able to resume operations from the 38th to the 44th or bottom level. It is the extensive flow of South Kearsarge water into Wolverine that necessitated the shortening of Wolverine's ropes and the temporary abandonment of operations below the 38th level. There is considerable ground yet to be worked in the six lowest levels, but the water makes it impossible to get below the 38th at present. Since Wolverine holed through to North Kearsarge the flow of water is so great that No. 1 shaft of the latter is used for bailing purposes and all hoisting is being done in No. 3 and 4. It is understood that Kearsarge has ordered three large electric pumps to take care of the water, and once this equipment is in operation a resump-

tion of ore-hoisting in No. 1 shaft can be looked for at once.

Kearsarge shows some slight improvement in tonnage since the curtailment at Allouez and Centennial and a further increase is looked for within another month for a large number of Allouez and Centennial employees have been transferred to Kearsarge. The increase in the force is estimated to be 60 men. Meantime, Allouez is gradually getting its stopes cleaned up, with rock shipments since the suspension averaging about 325 tons per day. No. 2 shaft now is undergoing repairs and as soon as the interior is re-lined with timber and otherwise overhauled, similar operations will be under way in No. 1. Ahmeek has absorbed the bulk of the Allouez and Centennial workers and an appreciable increase in the July production should be noted.

Calumet & Hecla's No. 16 shaft, Osceola amygdaloid, is hoisting on only one shift, employing about 50% of

and this section may get an adequate share of coal as a result of this arrangement. C. H. Benedict, metallurgist for Calumet & Hecla, is the northern Michigan member of the commission.

In connection with Mayflower's operations, the question of 'commercial rock' occasionally is raised. This may be answered briefly by the statement that the commercial value of rock can be determined only by a mill-test. Mayflower has about 1000 ft. of openings and less than one-third of the total are on the Mayflower vein. In the north drift, not more than 50 ft. was driven through the lode while in the south, the lode was opened by the drift, and eastward in the cross-cut. To the west, the cross-cut penetrated some vein matter, then entered trap and a mixture, breasting in the foot-wall trap. Grades in this region cannot be determined by assaying bits of rock, for the formations are too irregular. Accordingly the mill-test in a new section comes when a sufficient number

THE IRON CAP MILL AT COPPERHILL, ARIZONA

the normal force. The production of other Osceola-lode shafts has dropped proportionately, while shipments from the shafts on the conglomerate have not been as heavy as last winter or early in the spring. With the reclamation plant producing at the rate of close to 1,400,000 lb. of refined copper per month, decreases in rock-shipments are not felt seriously, and while the labor problem has been one of the most serious that the Michigan copper mines have had to solve for the past six years, the fuel shortage has presented even greater difficulties. Although shipments have been coming with greater frequency during the past week or ten days, receipts must be far greater if a winter's supply is to be put in storage before the navigation season closes. Far removed from the coalfields, the only economical way in which fuel can be shipped is by water, but other lake ports are crying just as loudly for help as the Michigan copper country. The State of Michigan, however, has taken a hand in the fuel situation by the appointment of a fuel commission,

of tons, probably 300 to 500 tons, of vein rock have been accumulated. It is Mayflower's intention to stock a sufficient quantity of rock to warrant a mill-run after the developments proceed farther. In the absence of such a test, the best barometer is the miners' experience as he sees the openings from day to day. The Mayflower lode contains fine copper, in granular form, and the miners who helped to sink the shaft are confident that where the formation is regular, the rock will be commercial.

NEVADA

DEVELOPMENT MILL AT GOLDFIELD IS TREATING 100 TONS PER DAY.

OREANA.—The Pershing County Mines Co. is buying machinery to be used in re-opening the Jersey mine, which is credited with a production in the '70s of \$200,000 to a depth of 75 ft. The company has an option on the Montezuma, from which a good production also was

made in the '70s. The company was promoted by Glenn D. Cook of Salt Lake City, and the principal stockholders are Salt Lake City men. Cook shipped \$75,000 worth of ore from dumps before organizing the company for deep work. A 100-ft. shaft on the Montezuma is to be sunk to 200 ft., where a cross-cut will be driven to the vein. In the early days a shaft sunk on the Montezuma passed out of the ore at a depth of 75 ft., but the ore, raking west, is reported to have been found in a drift that is now caved. The shoot was 100 ft. long and 5 to 15 ft. wide. The ore contained jamesonite, a sulph-antimonite of lead; bindheimite, an amorphous antimonate of lead formed by alteration of the jamesonite, cerussite, gypsum, and antimony. The Montezuma and Jersey mines are four miles from Oreana, which is on the Southern Pacific in Pershing county.

CARSON.—J. F. Shaughnessy, of the Nevada Public Service Commission, declares the 25% increase in freight rates granted to the railroads operating in the mountain States "will seriously cripple, if not destroy, Nevada's mining industry". He thinks the new rates will result in decreased revenue for the railroads operating in Nevada, as he says it will result in the closing of many mines now shipping. In illustration of this, he points to the Virginia Louise mine at Pioche, now giving the Los Angeles & Salt Lake road \$300,000 gross earnings annually. The Virginia Louise is operating on a profit of 50c. on each ton of ore shipped. Mr. Shaughnessy also said that the increased rates possibly will amount to more than the net earnings of the Nevada Consolidated at Ely. Mine operators of the State have feared the effect of the increase, as it will be felt not only by the companies shipping ore, but companies working prospects will be compelled to pay much more for everything used, from powder to food for the miners.

ARROWHEAD.—A 3-ft. width of ore assaying \$500 per ton has been opened in the 150-ft. west drift on the 100-ft. level of the Arrowhead, according to A. H. Elftman, consulting engineer to the company. Drifting has been started on the 267-ft., or bottom, level. The Consolidated is drifting from a cross-cut to the vein at a depth of 215 ft. Drifts are being driven east and west in a body of quartz giving low assay returns. J. H. Goodman and S. H. Williams of Ely have bought the Signal claims, adjoining the Arrowhead on the south-west and it is reported that they will organize a company to develop the group. A 100-ft. shaft was sunk by former owners and this can be continued by the new company.

ROCHESTER.—The mines here and the Nevada Packard are closed because of lack of power and they are not expected to re-open for more than a month. Electric power for the district is furnished by a company using water from the Lahontan reservoir at Fallon, which is practically exhausted.

ELY.—The Nevada Consolidated mined 791,151 tons of ore of an average value of \$3.27½ from April 1 to July 1. The gross value of the ore was \$2,591,348. Cost of management was \$47,562; mining, \$607,187; transportation, \$256,393; reduction and sales, \$1,438,237, making a total cost of \$2,349,379. The net realization was \$241,-

968. No ore was mined by the Coppermines company during the quarter. Royalties received from lessees amounted to \$2231 net. The cost of management was \$10,539 and mining, \$78,018, leaving a net loss of \$88,-557.

TOLICHA.—The W. J. Loring interests are negotiating for the purchase of the Southey group of claims, two miles from the Harney group. Southey has fixed the price at \$50,000 and he is in Goldfield awaiting the arrival of those who are expected to close the sale. Other sales of claims are reported to be pending on the strength of recent developments in drifts from the Harney tunnel.

GOLDFIELD.—The Silver Pick has secured a lease on practically all of the Red Top mine of the Development company, including the part in which a large tonnage was broken by the Development in two blasts about a year ago. The lease was granted because the Silver Pick can mine the ore more economically than the Development and return a better profit to the Development than if that company did the work, according to Mat Murphy, superintendent for the Silver Pick. The Development has no air-compressor available for this work and air from the Silver Pick can be used with little expense. The workings are in good condition and the Silver Pick expects to make a good production of ore assaying \$10 to \$20 from them, in addition to opening higher-grade ore in the foot-wall of the vein. The Pick is shipping regularly to the Development mill, which is treating daily 100 tons of ore from several sources.

The Deep Mines Co. has announced that the proposed 3000-ft. shaft will be sunk on the southern end of the Combiantion claim, east of the Atlanta. There is a two-compartment shaft at this point that is thought to be 400 to 600 ft. deep. This will be enlarged to four compartments and sinking will be started from it, with two shifts of miners employed. Nine men are building a road to the shaft and excavating for the foundation for a 75-hp. hoist, which will be used until sinking is started. The Merger equipment, capable of hoisting from 4000 ft., will then be used. H. G. McMahon, secretary for the company, says the exchange of stock "has been successful to a marked degree". The Kewanas has secured a lease from the Deep Mines. A small compressor will be used in driving a cross-cut from the 825-ft. level of the Merger shaft to prospect a vein that has produced ore from the surface to 300 ft., but which has not been prospected below that depth except by a cross-cut at 600 ft., which shows the vein to be 15 ft. wide. Assays as high as \$6 were secured in the cross-cut. Regular shipments of ore assaying \$12 to \$24 are being made to the Development mill from the Cracker Jack lease on the Florence.

UTAH

UTAH METAL PRODUCTION.

SALT LAKE CITY.—Some interesting figures on the mineral output of the State have been compiled by Henry M. Adkinson, mining engineer of Salt Lake City, from reports of the U. S. Geological Survey. Since the discovery of metal in Utah in 1863 to the close of 1919, the total

value of the gold output of Utah has been \$98,138,503; of silver, \$298,109,421; of copper, \$426,034,339; of lead, \$207,508,430; and of zinc, \$17,751,225, making a grand total of \$1,047,641,934. Up to the close of 1917, Bingham had an output of \$419,699,686; Park City, \$169,814,024; Tintic district, \$180,401,804, and forty-six other districts, \$146,239,823, making a grand total of \$916,155,337. The total value of the 1918 mineral output of the State was \$86,047,597 and of the 1919 output, \$45,439,000, but figures showing the distribution of these totals among the various mining camps have not yet been prepared.

EUREKA.—A mechanical shoveling machine, of a simple and practical type, has been developed at the Tintic Standard mine. So far as is known, this is the first time the device has been used underground. On the 1100-ft. level of the mine, in the main north-south mineral channel, a large stope of dry silicious silver ore, which averaged over 30 oz. in silver per ton, has been opened. A road-scraper, handled by two men, is being used to load the broken ore into mine-cars. A small air-hoist has been set up, from which is run a steel cable to the scraper. The scraper is loaded and hauled up on inclined slide to the cars by this cable. About two scraperloads fill a mine-car, and much hard labor is saved. On this level the temperature is so high that it is almost impossible for shovelers to work with comfort. This new stope of silicious ore on the 1100-ft. level is about 100 ft. west of No. 2 shaft. So far as present developments indicate, the ore is from 40 to 50 ft. wide. The ore-zone has been proved to a depth of 1400 ft.; on the 1450-ft. level, a raise has been put up for a distance of 50 ft. in a stope of high-grade galena, which contains considerable silver.

Shipments for the week ended July 31 totaled 146 cars, of which the Chief Consolidated shipped 46; Tintic Standard, 27; Eagle & Blue Bell, 15; Dragon, 10; Iron Blossom, 8; Mammoth, 7; Grand Central, 7; Iron King, 6; Gemini, 4; Victoria, 3; Swansea, 3; Bullion Beck, 3; Centennial Eureka, 3; Zuma, 1; Victor, 1; Alaska, 1; and Gold Chain, 1.

It is announced that the Knight interests will temporarily suspend work at the Tintic drain-tunnel. It is understood that this also means that operations will be suspended in the Ruby Hill shaft, which has been sunk to a depth of 700 ft. About 25 men are being employed in the tunnel and almost as many at the shaft. The Knight people state that they have no intention of abandoning the drain-tunnel, but the large stockholders do not feel like meeting the heavy assessments at the present time. It is hoped that work will be resumed by fall.

It is reported that one of the Salt Lake valley smelters is trying to make a deal for the treatment of the big mill-dump of the Mammoth Mining Co. Figures on file in the office of the company indicated that the dump contains 250,000 tons and that its metal content averages close to \$7 per ton on the basis of present metal prices.

The Mammoth is one of the pioneer properties in this camp, and at various times in the past, offers have been made the company for the treatment of the tailing, none of which has been accepted.

PARK CITY.—The Judge Mining & Smelting Co. has prepared plans for a new office building to supplant the one now occupied in Empire Canyon. In addition to office-rooms, there will be a large drafting-room, as well as change-rooms, equipped with the latest drying paraphernalia, shower-baths, etc., for the employees. The Park Utah company has its first lot of ore at the Daly-West loading-station awaiting transportation to the railway. Conditions at the property are reported as excellent. Shipments for the week ended July 31 totaled 1901 tons, as compared with 2349 tons for the preceding period. The Silver King Coalition shipped 693 tons; the Ontario 550 tons; the Judge M. & S., 419 tons; the Daly-West, 119 tons; Daly, 60 tons; and the Naildriver, 60 tons.

ALTA.—Unwatering of the workings of the Old Colum-

SIMON-CONTACT SHAFT NEAR MINA, NEVADA

bus Consolidated mine was accomplished recently by the connection made between the Wasatch Mines tunnel and the 400-ft. level. The Wasatch Mines tunnel was started not only for the purpose of tapping the Columbus workings at depth, but to furnish transportation and drainage for the other Alta mines. Some twenty years ago, the Columbus Consolidated was a producer of high-grade ore. When the 400-ft. level was reached, trouble with water prevented economical operation. All operations were suspended, and later the Wasatch Mines Co. acquired the property and started the main working-tunnel. When the face of the tunnel had been advanced 5538 ft. from the portal, a cross-cut was driven along the fissure 250 ft. back of the face until the Cardiff overthrust contact, in which the richest mineralization was found in the Columbus workings, was intersected. Drifting was started along this fissure. At a distance of approximately 500 ft. from the point at which the tunnel left the main adit, the contact was cut. On this contact a two-compartment, 9 by 5-ft. raise, has been made in

good milling ore. One foot of the ore is excellent shipping product, averaging \$70 per ton in gold, silver, lead, and copper. The management made the connection with the 400-ft. level 140 ft. above the cross-cut. When the connection was made, a flow of water, four feet deep in the adit, flowed for 24 hours. The No. 3 shaft had 70 ft. of water and several miles of drifts, tunnel, etc., were full of water.

WISCONSIN

DISTRICT IS STILL SHORT OF MINERS.

Higher average prices paid for zinc and lead ore maintained production through July in spite of critical labor conditions. Several large producers suspended output on account of an acute shortage of shovelers, and two others shut-down because their ore deposits were exhausted. The better tone in the slab-zinc market is the natural result of curtailed output of zinc ore in other districts, especially in the Tri-State region. A reserve in the Wisconsin field, conservatively estimated at 10,000 tons of green concentrate, is held principally by magnetic ore-separating plants and a few of the large zinc-operators. This reserve remained practically untouched through the month of July and should price offerings for high-grade blende continue at the base reported for this month it is probable that this reserve will be disposed of quickly. While there was a feeling of gloom spread over the field prior to July 1, this gave way to a more cheerful attitude as prices began to climb, and the close of the month found many with the disposition to renew exploration work, undertake new construction, and extend the scope of operations generally. The fly in the ointment is the scarcity of shovelers. Many competent miners have been attracted to the harvest fields, and not until one of the best crops known to the district is gathered will there be any relief from this quarter. Negroes have been obtained in fair numbers and it is said they develop into good miners. Wages are the highest ever known to the field and husky shovelers willing to work can on contract earn as high as \$12 per shift.

High-grade refinery blende opened up the first week of the month on a base of \$48 per ton. Production of raw ore at mills ran close to 3300 tons for the week, and, strangely, as fast as offerings advanced production decreased. The scarcity of men was responsible. On July 10 offerings were advanced to \$49.25 per ton, base, and penalties were not considered. On July 24 the price advanced to \$53, with the latitude on zinc assays widened. The closing week saw high-grade zinc ore selling on a range of \$51 to \$53, with choice grades in good demand. The recovery of low-grade zinc ore fell to 2000 tons per week during the last three weeks of the month and it is safe to say that under present conditions not much larger yield may be anticipated. Only the larger and better deposits are being mined where working forces are not normal.

Lead ore, which ruled high this year at \$110 per ton, suffered repeated cuts until the price was brought down at the beginning of the month to \$90 per ton, 80% metal

content. About mid-month an advance was made, bringing the price back to \$92.50 per ton. Without much prior notice another advance came quickly to \$100. A growing scarcity of ore is mainly responsible for the advance in the price of supplies available, but a shortage is evident as the lowered production of zinc mill-feed is mainly responsible for the decreased output of lead ore. No published figures were given out in the closing days of the month, but lead-ore buyers were scouring the district for stocks and offerings had advanced to \$104 for choice lead concentrate. It was predicted freely that the ground lost would be recovered shortly and that lead ore would again command the high price of earlier in the year, namely, \$110 per ton. The reserve in the field at the close of the month exceeded 1000 tons of lead concentrate. The lead deposits for which the Wisconsin field was famous in early days seem to have been well searched out by the pioneer miners.

Iron pyrite is in poor demand, the only shipper being the Zinc Concentrating Co., of New York, with deliveries to the General Chemical Co. The operation of a new sulphuric-acid plant for the Vinegar Hill interests, at Cuba City, was thought would benefit the market, but this conclusion was wrong. The fumes necessary to manufacture acid are taken up in the process of zinc-ore separation and raw pyrite is not necessary. Shipments of carbonate-zinc ore were low and confined to clean-up shipments, as the mines have all suspended operations in the northern districts of the field, from which this grade of ore has been principally obtained.

Deliveries by districts, for July, to magnetic separating plants in the field were made as follows:

District	Zinc ore, lb	Lead ore, lb.
Benton	9,830,000	304,000
Livingston	6,068,000	60,000
Cuba City	2,808,000	102,000
Galena	1,802,000	236,000
Platteville	1,286,400
Shullsburg	1,164,000	70,000
Hazel Green	552,000
Day Siding	538,000
Highlands	240,000
Linden	500,000
Total	24,788,400	772,000

The recovery of milled concentrate for the month at mines amounted to 12,394 tons, all ore being disposed of on current output. Net deliveries of high-grade blende shipped to smelters amounted to 7205 tons, distributed as follows:

Company	Lb.
Mineral Point Zinc Co.	7,202,000
National Ore Separators	3,470,000
Wisconsin Zinc Co.	2,406,000
Block-House Mining Co.	804,000
Zinc Concentrating Co.	528,000
Total	14,410,000

The closing down of the Champion mine, in the Benton district, on account of a shortage of shovelers removed the best individual producer in the field. The mine has averaged 300 to 400 tons of zinc concentrate weekly. The Blewett mine, in the Galena district, also shut-down; the low price for 40% zinc concentrate was stated as the cause for the suspension. The Bull Moose mine resumed shipments, for the time being at least, in order to relieve congestion at ore-bins.

BRITISH COLUMBIA

REPORT OF SILVERSMITH MINES, LTD.

SLOCAN.—The report of the SilverSmith Mines, Ltd., for the year ended May 31, 1920, shows that 13,400 tons of ore was mined during the year, producing 280 tons of shipping ore, 834 tons of lead concentrate, and 968 tons of zinc concentrate. The total income from ore and concentrate was \$205,996 and the net profit \$14,350. A shortage of water, due to severe frost early in the winter, necessitated the closing of the mill on December 2, and the unusually late spring prevented it being re-started before May 13. Added to this loss of five months at the mill, the mine and mill were closed by a strike for two weeks. But for these two causes the output of concentrate would have been considerably greater, which is demonstrated by the fact that since the re-starting of the mill more than \$100,000 has been received for sale of concentrate. This, however, goes into next year's account. The mine is in excellent physical condition. The ore-shoot that was found on No. 10 level in 1918 has been developed on No. 8 level, where it is as strong and rich as on No. 10. It is estimated that enough ore has been proved to keep the mill running at its present capacity for the next seven years. L. H. Bigger, of Montreal, has purchased Pat McGuire's share in the Ottawa mine, and will place a mill of his own design on the property. Mr. Bigger is in Montreal financing the enterprise. Mr. Griffin and associates have found a strong vein of silver-lead ore on Lincoln creek. George Aylard and his associates in the Standard mine have taken a lease and option on the Wellington property, in the Whitewater district. The Standard mine is known to be approaching exhaustion, the vigorous development of the last two years having disclosed nothing of a lasting nature. The owners of the property, therefore, are anxious to find another mine to provide feed for their mill and employment for their staff. The last dividend was passed and some \$300,000 set aside for this purpose. There is much activity in Kaslo camp.

VANCOUVER.—J. W. D. Moodie has resigned from the management of the Britannia mine, and, after a long holiday, will reside in California. B. B. Nieding, who has been operating mines in the State of Washington, has been appointed to fill Mr. Moodie's place. Mr. Moodie has been in charge of the Britannia for many years, and his foresight and energy have done much toward placing the mine in its present excellent physical state. The British Columbia 'Gazette' shows that five or six mining companies are being organized each week in this city.

PRINCE RUPERT.—H. Smith, representative of the American Smelting & Refining Co., has made an examination and sampling of the Sunrise mine, at Nine-mile mountain, which the company has under option. Prospectors are active at Kleanza mountain, near Usk; Linderland and Wells have started work on the Peerless group, at the head of Kleanza creek; Bell and Gall are developing the Sunset group. High-grade ore is being developed by J. D. Wells, at the New Era group, near Usk. To facilitate prospecting, work is to be started at once on a

trail up Kleanza creek. Good samples have been taken from the Hole in the Ground group, near Prince George. The vein has been traced for 600 ft. The tunnel at the Babine Bonanza mine, in the Telkwa section, is now in 850 ft. During the last 75 ft. of driving the vein has widened from six inches to two feet, and is good milling ore.

VICTORIA.—It is understood that, owing to the high cost of labor and supplies and the unsatisfactory condition of the copper market, the Consolidated Mining & Smelting Co. will defer the erection of a concentrating plant at the Sunloch mine, about 40 miles from here. Development work will be continued at the mine. A contract for diamond-drilling has been let to the Diamond Drill Contracting Co., of Spokane, and the drills are being shipped to the mine.

STEWART.—R. K. Neil, part owner of the Premier mine,

NEAR THE BRITANNIA MINE, BRITISH COLUMBIA

in discussing operations on that property, stated that a cyanide plant, with a capacity of 100 tons per day, is being installed and would be ready for use early next year.

There are some 100 claims staked in the Marmot River district and on many, development work is in progress. George Clothier, government mining engineer, recently made a tour of inspection through the district with a view to ascertaining the extent of the necessary road and trail improvements. The B. C. Exploration Co. is heavily interested in this section and W. L. Uglow, geologist for the company, has completed an examination and is preparing a report. P. D. I. Honeyman, for the same company, has a small crew of men at work on the Salmon River Lode Mining Co.'s property, situated near the Big Missouri group. Among the properties under development in the Bear River valley are the Bayview, situated just back of Stewart, from which a trial shipment is to be made soon;

the Lakeview, which is being worked by Al. Harris on behalf of P. Welch and associates; the Fitzgerald group, which is to be explored by diamond-drill by the Algonician Development Co.; and the Nabob and Redtop groups.

ALICE ARM.—The Dolly Varden is shipping an average of 150 tons of ore per day and preparations are being made for the extension of the railway to the Wolf claims situated a short distance north of the mine. The Torie, Tiger, Musk, Silver Horde, Climax, and other prospects are being opened up. Surface-stripping is being done on the La Rose group with satisfactory results and good showings are reported on the Wild Cat, North Star, and Royal groups.

QUESNEL.—Once again R. T. Ward, of the Bullion Placer Leases, has been heard of in connection with litigation. Having won his long drawn-out suit with John Hopp it was thought that the operation of the long disputed property would follow without delay. Some of Ward's associates, however, challenged his right to retain control or the management of the project. For a time it looked as though there might be another sustained fight through the courts. However, it now appears that a settlement, said to be generally satisfactory, has been reached and that the well known property soon will be put on an operating basis.

ONTARIO

SILVER BEING STORED AT COBALT.

COBALT.—At the time of writing, silver stocks at the mines of Cobalt are increasing. A total of about three million ounces of bullion is stored in the local vaults. Using cars with a capacity of 30 tons each, four such carloads of refined silver are being held pending higher prices. The Nipissing alone has nearly two carloads. It is believed that if silver producers in other countries would adopt a similar policy they would frustrate the designs of certain financial interests to hold the price of silver down. An incident of peculiar interest is the discovery of gold-bearing quartz at a depth of 800 ft. on the Crown Reserve mine where heretofore native silver has been the only precious metal. Gold assays run as high as \$12 per ton, but the quantity is decidedly limited.

Oil-flotation equipment, being installed at the Temiskaming plant, is expected to be ready to operate by the end of September. Although this company has not paid any dividends so far this year, it is learned that the surplus amounts to nearly \$1,000,000. This compares with \$864,016 at the end of 1919. It is understood another dividend disbursement is under consideration similar to that of 4%, made in December of last year.

The construction of an 80-ton mill on the Keeley Silver Mines in South Lorrain is proceeding satisfactorily, and production is expected to commence within the next 90 days. Underground work is steadily adding to the amount of ore in sight, and the indications are that mill-heads may average between 30 and 40 oz. silver per ton.

Attracted by reports of a rich silver discovery thirty miles from Amos, in north-western Quebec, a large num-

ber of prospectors from the Cobalt district joined in a rush to that field. They allege that after examining the find, it is evident to them that the silver was placed there by human agencies.

The shaft on the Oxford-Cobalt property is to be continued from the present point of 150 ft. to 250 ft. Only lean silver ore has been found on the 150-ft. level. No silver discoveries have so far been reported as a result of throwing the Gillies Limit open for prospecting, although quite a number of claims have been staked.

PORCUPINE.—Figures covering the second quarter show that mining costs have been increased to a considerably greater extent than was anticipated. At the Hollinger Consolidated it was estimated that the increased rate of wages would add about 25c. per ton to the cost of treatment, but the actual increase is more than double that amount. It had been expected that the higher pay would attract larger forces, and that increased efficiency would hold the extra cost down to 25c. per ton, but the increased efficiency has not been apparent. It is realized, however, that the raising of wages was necessary in order to prevent a further decline in the number of men employed, and that otherwise the company might not have been able to 'carry-on' even at the present reduced capacity. 'As costs last year at the Hollinger averaged close upon \$5 per ton, the figure this year will probably be about \$5.50.

The McIntyre has opened up for nearly a quarter of a mile vein No. 5 at the 1125-ft. level, where it has a width of from 9 to 10 ft. with gold content averaging \$18 to the ton. The orebody extends into the Jupiter claim. The shareholders of the Porcupine Vipond-North Thompson have ratified the proposed sale of 600,000 shares of treasury stock to a syndicate represented by Hamilton B. Wills. Immediate delivery is to be made of 200,000 shares at 15c., the purchasers holding an option on 200,000 more at 30c. at six months, and a further option on another 200,000 at ten months at 50c. The mine will be re-opened soon.

In the early days of the Poreupine camp Bewick, Moreing Co., an English concern, secured a large number of claims and a large block of Hollinger stock. It disposed of the latter to considerable advantage, but the outbreak of the War prevented the working of its properties. It is now stated that a new company is being organized to take over the Bewick-Moreing interests, and that financial arrangements have been effected which will enable them to operate.

KIRKLAND LAKE.—At the Bidgood, the vein on which the main shaft was sunk dipped out of the shaft. It was tapped by a cross-cut 70 ft. in length at the 200-ft. level, where it was found to have widened out to 16 ft. A vein some distance from the shaft on the surface dipped into the workings at a depth of 240 ft. It shows a width of 25 ft. and is being sampled as the work proceeds.

Rapid progress is being made with the mill of Wright-Hargreaves, which will be the largest in the district with a daily capacity of from 150 to 200 tons. The structure is almost completed, and the equipment is being installed—two crushers, a ball-mill, and two tube-mills are now in place.

THE MINING SUMMARY

CALIFORNIA

Bishop.—Preparations are being made to start the mill on the Wilshire gold property about the end of September. A force of 60 men has been steadily at work developing the mine since last May in order to furnish the mill with a continuous supply of ore at the rate of 150 tons per day. A body of ore 420 ft. long and about 15 ft. wide with an average gold content of \$11 has been developed on the second level with ore still in both faces. Crushing will be done with an Allis-Chalmers ball-mill, which will be followed by K & K flotation machines.

Redding.—Erection of the building recently purchased from the Balaklala Copper Co. by the Shasta Zinc & Copper Co. will start at Winthrop in a short time. Dismantling of the structures at Coram, including the old Balaklala smelter, which cost upward of \$1,000,000, is to start this week and the material will be moved to Winthrop as rapidly as possible. Considerable work has begun near Winthrop with more men employed as they can be obtained. The Shasta Zinc & Copper Co., controlled by the Jackling interests, has taken an option on the Arps and Michigan groups, in the Bully Hill region, and is reported negotiating for other nearby properties. On the bottom levels of the Bully Hill mine a large deposit of high-grade ore has been exposed with zinc largely predominating. Plans of the company include erection of a reduction plant and a heavy output of zinc and copper. Some silver and gold are also found.

Sonora.—Operations have been suspended at the Shawmut mine, the largest producer in Tuolumne county, by the Belmont Development Co. of Tonopah. It is stated that although the ore is of good grade with a large tonnage blocked out, the steadily mounting labor and material costs have made closing of the property advisable. A small force will be kept at work to keep the shaft unwatered and in repair. The Shawmut is one of the famous Mother Lode mines and produced millions before passing into the control of the Belmont company. Under the new control the shaft was deepened, new ore deposits opened, and mine-plant and mill greatly improved. It is stated that operations on the old-time scale will be resumed as soon as gold mining approaches its pre-war status.—A large mill has been erected on the Morning Star group, formerly the Boston, seven miles southeast of Jackson. The property contains large bodies of medium-grade ore near surface and the ground is to be worked on a large scale. The Boston was long noted for its yield of rich ore, but much medium-grade product is said to have been ignored by early-day operators. New York capitalists control the property.

IDAHO

Coeur d'Alene.—The Jack Waite company, in the Coeur d'Alene, has commenced hauling ore from its mine, 13 miles to Prichard, making two trips per day. The mine has several cars of ore ready to be hauled for shipment to the smelter. Some of the ore is first class and some hand-jigged. The ore runs 65 to 70% lead, with 5 to 7 oz. silver per ton.—The Hecla Mining Co. is shipping 2700 to 2800 tons of high-grade crude ore and concentrate per month, according to James F. McCarthy, president and general manager. It

is hoisting 600 to 700 tons daily. The mine and mill are operated on a basis of six days per week. Three hundred men are employed. The orebody opened on the 2000-ft. level of the main workings has been followed by drifting for 500 ft. It is 16 ft. wide and contains ore like that on the 1600-ft. level, the next above, in which the grade is good. The drift on this level is 1600 ft. long, considerable work having been done before the ore was reached.—Movement of ore by truck from the Idaho-Continental to the railway at Porthill, 26 miles distant, has been resumed. Four trucks are required in addition to the eight owned by the company; 1300 tons of lead-silver concentrate, slime, and crude ore has been accumulated in the period of suspended hauling, and slime and concentrate at the rate of 20 tons daily is being made. Eight trucks will haul 50 tons per day by making eight round trips. The company has a full crew of miners and shovelers, but needs mill men and several road repairmen; 125 men are employed at present.

MISSOURI

Joplin.—What is considered one of the most remarkable drill-holes ever completed in the district is that on the Acme lease of the Hurlbut land, a block of the Butte-Kansas Mining Co.'s holdings. Ore was entered in the hole at 155 ft. and continued with more or less richness to a depth of 365 ft.—or a continuous run of 210 ft. The average assay for this deposit was 6.54% zinc. Cuttings were taken from every five feet of drilling. With the exception of a few feet, the entire orebody is considered workable. The lease, a 40-acre tract, is situated west of the Waco No. 2 mill, operated by the Barnsdall interests. L. P. Buchanan of Joplin is manager of the Butte-Kansas. The discovery is a continuation of the big deposits that have been developed in the Waco field, and the orebodies are believed to be the largest yet developed in the Joplin district.

Practically the same run of ore obtained on the Butte-Kansas lease was found on the Waco No. 2 and the High Five properties, controlled by Franks and Dangle. Other big deposits have been blocked out on portions of the 400-acre tract controlled by Franks and Dangle.

Three drill-holes have been completed on the Gascho lease on the Olsen land, which show an average assay of ore of 5.98% between 300 and 350 ft. An average face of 35 ft. was developed.

NEVADA

Beatty.—The Continental Fluorspar Co., operating in the Bare mountains, has discharged all of the miners and practically has closed until new machinery can be secured. The grinder has caused trouble by the fluorspar caking in it and it is reported that clay mixed with the fluorspar has been found in larger quantity than usual in recent work. The company expects to resume in a month with a new grinder.

Cactus.—Drifts on the 265-ft., or bottom level, of the Cactus Nevada continue to open ore of erratic value, but which could be treated at a good profit in a mill on the claims. Some rich ore is being found in small lenses. The Cactus Leona is preparing to start work.

Montezuma.—The Montezuma Silver mine has been closed, the reason given being bad roads. It is rumored that a

shake-up of officials is due and that the real reason for the closing is dissatisfaction of the New York men interested with recent expenses, which are said to have been unusually heavy.

Virginia City.—An air-compressor has been erected at the place on American flat from which driving of the tunnel of the United Comstock Mines Co. will be started from the surface. The tunnel also will be driven from several old shafts. The mill to be built by the company will be constructed on American flat at the portal of the tunnel, which will be 8 ft. wide and 8 ft. high. The shafts are being put in condition so that driving can be started from them. The Imperial shaft has been sunk to 575 ft., the depth from which the tunnel will be driven. It is planned to replace the steam-hoist used for years at the C. & C., one of the north end mines, with a 400-hp. electric hoist, which will result in an estimated saving of \$40,000 yearly. The vein has been entered in a cross-cut from the 370-ft. shaft of the Comstock Silver Mining Co. The cross-cut is being continued through the vein and low assays are being secured.

WASHINGTON

Stevens County.—Nine chimneys have been opened on the property of the Gladstone Mountain company, and in eight of them lead ore has been found. Some sulphide and carbonate exists in all. Chimney No. 2, in which a 100-ft. shaft has been sunk, has yielded three or more carloads of lead sulphide with a net value of \$83 to \$98 per ton. A carload of 46 tons, shipped recently, returned \$4488 net. The carbonate ore removed from the several chimneys lies on the dump for the present. From the No. 8 chimney, a carload of lead sulphide has been shipped, another prepared for shipment, and a carload of carbonate will be shipped. This ore was removed from a shaft that penetrates the body for 20 ft. vertically and has an area of 8 by 8 ft. Some of the chimneys will be followed by shafts and others will be explored by drifts from a depth of 100 ft. The ore removed by the Gladstone in the last 10 months has supplied all the money used in exploration except that advanced to start the work and install equipment.—Several carloads of high-grade zinc ore have been mined from the vein opened recently on the Makie farm, on Deep creek, near Northport. The ore is carbonate and has a zinc content of 45%. The body is five feet wide and is not in a lime formation. Operators are proceeding with development. The comparatively short distance to a rail-point has added interest to the deposit.—The Lead Trust mine recently obtained a bond and lease on a timber claim near the mine and has found ore on it, according to reports. Ore containing lead has been disclosed at the surface and is being followed by a tunnel.

MEXICO

Sonora.—North of Las Chispas the Sulza Mining Co. is opening two shafts on the extension of the Chispas vein. One shaft is down 80 ft. and has yielded ore containing 175 oz. silver per ton. The owners of the Keystone property, west of Las Chispas, have opened negotiations to lease the Purisima claim of the Minas Pedrazzini Co., which adjoins their holdings, and have also started a cross-cut adit in the Keystone. The Espiritu Santo people have sent their engineer and geologist to inspect and report upon their claims situated south of here. The Bavianora property, next to the Keystone, may be re-opened soon. The Ilusion, a small prospect in Las Chispas, is sinking a test-pit, that shows promising ore assaying up to 40 oz. silver and 0.5 oz. gold per ton. In the Las Chispas mine the bonanza opened last December continues to produce. Shipments of 25 to 40 tons have been made every 20 days, with assay returns ranging from 350 to 850 oz. silver and 2.75 to 7 oz. gold per ton, besides some special sulphide fine with 15,000 oz. per ton. All of this is hand-sorted ore.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Adolph Knopf is at Mina, Nevada.

K. C. Parrish is at Barranquilla, Colombia.

Lyman H. Brooks Jr. has gone to Cooke City, Montana.

Askin Nicholas, formerly of New York, is at Brisbane, Australia.

John W. Mercer is making a short stay in Denver on his way to New York.

Charles E. Newton, of the Oregon School of Mines, at Corvallis, was here last week.

A. E. Drucker is examining copper mines in the Olympic mountains, Washington.

L. F. S. Holland is superintendent for the Crater Mining Co., at Winslow, Arizona.

John Roger, of New York, and **Walter H. Bunce**, of Los Angeles, called on August 4.

H. C. Hoover is on his way from Palo Alto to Minneapolis, to attend the Institute meeting.

J. C. Vidmar, mining engineer with the Chile Copper Co. at Chuquicamata, Chile, is in Arizona.

C. B. Lakenan, general manager for the Nevada Con. Copper Co., was in Salt Lake City last week.

Clarence A. Wright, recently associated with the Salt Lake City branch of the U. S. Bureau of Mines, is in Italy.

W. H. Wellman, superintendent for the 85 Mining Co., at Valedon, New Mexico, has moved to Parral, Mexico.

W. W. Norton, superintendent of the A. S. & R. Co.'s smelter at Murray, Utah, is taking a vacation in Europe.

Ing. S. Postnikoff, manager of the Bogoslovsk mining estate in the Ural region, is visiting reduction works in Utah and Montana.

Lester S. Grant, professor of mining in the Colorado School of Mines, has been visiting mining and metallurgical plants in Utah.

P. A. Simon, president and general manager for the Simon Silver-Lead Mines Co. at Mina, Nevada, has returned from a trip to New York.

E. L. Newhouse Jr., manager of the ore-purchasing department of the Utah branch of the A. S. & R. Co., spent several days in Nevada recently.

A. G. Burritt, geologist, and **H. A. Linke**, engineer, of Salt Lake City, are making a geological survey of the Fossil oil-fields near Kemmerer, Wyoming.

T. C. Botterill, formerly assistant superintendent of the Surf Inlet mine, has accepted the superintendency of the Emancipation mine, operated by the Liberator Mining Co.

J. W. D. Moodie, for many years general manager of the Britannia mine, has resigned. He is succeeded by **B. B. Nieding**, recently with the United Verde Extension, in Arizona.

Alfred T. Hastings, formerly general manager for the Bingham-Coalition Mines Co., at Bingham, Utah, is now assistant manager for the Phosphate Mining Co. at Nichols, Florida.

A. W. Fahrenwald has been appointed ore-dressing engineer with the U. S. Bureau of Mines in charge of the Moscow station, Idaho. He is conducting differential flotation tests in the mills of the Coeur d'Alene.

George S. Rice, chief mining engineer for the U. S. Bureau of Mines, addressed the San Francisco section of the A. I. M. & M. E. on August 6. His subject was 'Liquid Oxygen as a Commercial Explosive'.

THE METAL MARKET

Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

August 9.—Copper is inactive but firm. Lead is dull but steady. Zinc is quiet and firmer.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.85 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE MERCHANT MARINE

Provisions of the Merchant Marine Act giving preferential rail-rates on export and import commodities carried in American bottoms are in line with practices adopted in Germany, Japan, France, Spain, and other countries. Admiral Benson, chairman of the United States Shipping Board, declared in a recent letter.

These provisions were inserted by Congress at the request of the Shipping Board. Admiral Benson said, and are designed to offset "the countless discriminations by other nations against American shipping with which the Shipping Board ships and privately owned vessels of the United States have had to contend.

"Allowing a differential export-rate lower than the domestic rate upon rail-shipments within the country is purely a domestic prerogative," the chairman declared. "Each nation may unquestionably determine for itself that such rates may be made and that they shall be limited in application to cargo carried in vessels of its nationals. The Board of Trade report to the British government made in 1918 regarding shipping policies conceded that the control of such practice cannot properly be made the subject of a treaty."

Admiral Benson's letter was in reply to one from W. T. Christensen, of Seattle, who declared that since the major part of the Oriental commerce with Puget Sound was carried by foreign vessels, the enforcement of the discriminatory features of the Merchant Marine Act might result in the diversion of that commerce to Canadian ports. Admiral Benson said that threats of foreign carriers to transfer their Pacific Coast operations to Vancouver, should preferential rates be granted for American ships, were not worthy of consideration.

"Unless American ships be substituted for foreign ships in carrying of the greater part of your Oriental commerce the shipyards of Puget Sound which have given employment to many thousands of workmen, bringing abundant prosperity to your community, must close their gates, dismiss their employees, and as an industry cease to exist. Few if any repairs to foreign shipping are made in American yards, nor does the use in our trade with foreign ships encourage the building of American ships in American yards, the benefits of which should be apparent to the merchants in other business interests of Puget Sound."

Discussing the giving of preferential rates in other countries, the chairman said that France had given a 20% discount upon export-freight moving in French vessels to New York and other ports, including those of Great Britain, and that Spain also was using that method along with many other preferentials in the way of subsidies and subventions with Spanish ships. "Japanese ships in the past," he said, "were able to quote the same rates to interior points in Japan as other nations were able to quote to the seaports of that country, a differential quite sufficient to have enabled them in the absence of like preferential rates within the United States for our own ships, to control the rail-routings within the United States, and they have done so in many instances to the disadvantage of American ships and at times to certain American ports."

MONEY AND EXCHANGE

Foreign quotations on August 10 are as follows:

Sterling, dollars: Cable	3.63 1/2
" Demand	3.64 1/2
France, cents: Cable	7.30
" Demand	7.32
Lire, cents: Demand	5.13
Marks, cents: Demand	2.25

Eastern Metal Market

New York, August 4.

Very little activity is reported in any of the markets. Prices are firm in most cases. Increased freight-rates are expected to advance prices ultimately.

Demand for copper is moderate for domestic consumption but fairly good for export. Prices are firm.

The tin market is stagnant, and prices are nearly nominal but steady.

Not much business is reported in lead but prices are still firm and strong.

The zinc market is lifeless and prices have declined.

Antimony is unchanged.

IRON AND STEEL

The steel trade, which indulged in some ill-starred hopes of large orders when the railroads were returned to their owners in March, is making few predictions as to the new business to flow from the large freight-rate increase granted this week, according to 'The Iron Age'. It is evident that time will be required for building up earnings and that financing will not be made easy at once.

How the freight advance will affect prices of pig-iron and of steel products is widely discussed. Some grades of pig-iron have advanced \$4 in the past two months and from \$15 to \$18 in the past year. Fuel and transportation conditions have done this and they are still controlling factors. In comparison, the advance of \$1 to \$1.50 in pig-iron costs in the Middle West, due to the new freight rates, is insignificant.

Pig-iron production in July held up better than was expected in view of the railroad blockades. The total 3,067,043 tons, or 98,937 tons per day, against 3,043,540 tons in June, or 101,451 tons per day. The falling off was thus about 2500 tons per day. But July ran 2600 tons per day ahead of May and 7600 tons per day more than April. There was a net loss of nine furnaces last month.

COPPER

There has been little change in buying-power and no change in prices. Domestic consumers are not active in purchases, but foreign buyers are more so and the volume of this business is substantial. The increase in freight rates is expected to advance costs as well as freight-charges and hence the price of copper, lead, and zinc, but how, or when, no one knows. There is a possibility that buying for early delivery may speed up because of this, but there are no evidences yet. Leading producers of Lake and electrolytic copper maintain their prices firm at 19c., New York, for August and in some cases for September delivery. The outside market is quiet and inactive with limited quantities obtainable at around 18.75c., New York.

ZINC

Prime Western for August or September delivery has eased off to 7.70c., St. Louis, or 8.05c., New York, a decline of about 15 points in the week. This is due largely to a light demand. Buying is only hand-to-mouth and confined to a few galvanizers and brass-makers who are purchasing only for immediate needs. There is no disposition on the part of producers to sell beyond September, and some not that far, because of the effect of the new freight rates.

LEAD

The interesting news in this market is the rumor that a substantial amount of lead is on the seas from England consigned to New York. The effect of its arrival is causing speculation and it is predicted that the New York market,

when offered this lead, will fall-off and may reach a level as low or lower than St. Louis. It even might reach to the level of the American Smelting & Refining Co.. One cause for this opinion is the radical change in this market where the good demand has vanished and offerings of domestic lead in small quantities have been unabsorbed. Some business has been done at 9c., St. Louis, for prompt shipment and lead in transit and spot delivery has been sold at 9c., New York. We quote the market as largely nominal at 8.75c., St. Louis, or 9c., New York, with that of the leading interest unchanged at 8.25c., St. Louis, or 8.50c., New York.

TIN

There has been only enough business done to establish prices which have been relatively steady around 48c., New York, for spot Straits. Consumers still remain out of the market, which is almost lifeless. Offerings of spot-delivery Straits are light; this constitutes the only outstanding fact and it is evident that it would not take much buying initiative to send prices up. An interesting development is that speculators are letting the market drift. There was a holiday in London on Monday which intensified the dullness here, and there has been little doing since. Spot Straits there yesterday was quoted at £280 per ton with spot and future standard tin at £273 and £278, respectively. The New York quotation for spot Straits was 48.50c., yesterday. Tin arrivals in July are officially reported as 3870 tons, with 5530 tons delivered into consumption, the amount in stocks and landing July 31 having been 1926 tons. Arrivals thus far in August have been 1910 tons with 3065 tons afloat.

ANTIMONY

The market is unchanged except that there is a pressure to sell spot stocks. Quotations for wholesale lots for early delivery are 7.25c., New York, duty paid.

ALUMINUM

Conditions are nominal with quotations unchanged at 33c. from the leading interest and 31.50c., New York, from other sellers for virgin metal, 98 to 99% pure in wholesale lots for early delivery.

ORES

Tungsten: As compared with recent weeks a fair business has been done and negotiations for further business are reported. Chinese ore is quoted at \$5.25 per unit with Bolivian ore at \$6.50.

Ferro-tungsten is quoted at 80c. to \$1.10 per pound of contained tungsten.

Molybdenum: The market is quiet with inquiry somewhat better. Sellers are asking 75c. per pound of MoS₂ in regular concentrate with 60c. offered.

Manganese: Quotations are nominal at 70c. per unit, with offerings at 75c. Importations in June are officially reported as 80,329 gross tons or the largest in many months. This brings the total for the first half to 216,542 tons, or 36,090 tons per month.

Manganese-Iron Alloys: Offerings of Japanese ferro-manganese are reported to have eased off the spot quotation, which has been \$225, delivered. This foreign alloy is offered at \$185 seaboard. The last half quotation is still \$300, delivered. Inquiries are few, although some small prompt lots have sold at \$225. Importations in June were 5694 tons or the largest in many months. Exports were 275 tons in June, making the total for the fiscal year 2374 tons against 2184 tons for the fiscal year of 1919. The spiegeleisen market is stronger with \$80, furnace, asked and with inquiries totaling 3000 tons and 600 tons sold to domestic consumers.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

MINING NITRATES IN CHILE

By P. A. Raymond

Chile has been producing nitrate from its northern pampas for more than 50 years. It is natural that in the beginning the work was done in a primitive way, both with reference to extraction and elaboration. Of late years improvements have been made both in the transportation of the raw material to the elaboration plant and in its elaboration, but the methods of drilling and blasting has changed but little. The nitrate is produced from a material known in Chile as 'caliche', which lies in a horizontal stratum covered by an overburden of 'costra' and sometimes other rock. Costra is a rock that is impregnated with nitrate and might be considered a low-grade ore. The formation is broken, and contains seams, fissures, and vug-holes. The method of working has been to open up trenches, locally known as

sent a representative to Chile, and he, like many others, saw the big opportunities for the use of steam-shovels, drag-line scrapers, etc. After looking over the conditions he succeeded in placing two steam-shovels of the Thew automatic portable type for handling old worked-over material, but, like other engineers, he found himself handicapped with the problem of drilling and shooting the material in place sufficiently fast to make a shovel work efficiently. It will readily

Fig. 1. Methods of Mining Nitrate

'rajos'. These trenches are then widened, making a quarry-like hole called a 'calichera'. The depth of the trenches depends upon the depth of the strata or caliche or costra, ranging from 6 to 30 ft. The method is to go back from the face from 6 to 18 ft., according to conditions, and drill a hole as shown in Fig. 1.

These holes are dug by hand in the following manner: A hand-drilled hole is put down to the point marked 'A'; it is blasted and cleaned out. Then the driller proceeds to dig a hole from 6 to 8 in. diam. until he strikes the caliche, after which he forms what is known as a 'tasa', which gives the same condition as a sprung hole in quarry work. The tools used are a single-hand hammer, hand-steel, punch-bars with points formed at different angles, and a steel spoon 3 or 4 in. diam. fastened to a stock 6 to 12 ft. long. The hole is afterward loaded with black-powder as shown in the sketch mentioned. The above work represents from 2 to 6 days for one workman, and will break from 700 to 1000 cu. ft. of material, leaving many large boulders which are afterward block-holed by hand or broken up with a 16-lb. double-hand hammer. This material is afterward sorted by hand by men who work at a certain price per carload, the barren rock being thrown to one side.

About two years ago the Allied Machinery Co. of America

Native Workman and Turbo Drill

be seen that 1000 cu. ft. of material drilled and shot in three days will not keep a shovel busy.

Manufacturers of drills in both Europe and America had tried to solve the problem. Nearly every type of drill, including piston-drills, hammer-drills, churn-drills, and diamond-drills had been tried and all failed for one cause or another. The water question eliminated the piston and churn-drills, the hammer-drills failed for the reason that in all hammer-drills the rotation was dependent on the action of the hammer, causing the steel to stick when striking open fissures, vug-holes, or hard pebbles.

I made a visit last August to some eighteen or twenty properties and I wish to say that every assistance was given by the Chileans toward a thorough study of the question. After going over the data, including the reasons for previous failures, it was decided to try out the Turbro drill, manufactured by the Denver Rock Drill Manufacturing Co. of Denver, for the reason that it is of a portable type (plain tripod-mounting), and that by a small change in the air-connections it could be made to use compressed air instead of water through the steel to expel the cuttings. Moreover, the rotation is independent of the action of the hammer or piston.

After the manager of the Peña Grande property, owned by the Dupont Nitrate Co., was good enough to agree to allow us to use compressed air from its power-plant, reports and recommendations were sent to the Denver Rock Drill Co., specifying steel for holes 6 in. diam. A Turbro drill with tripod and different types of drill-bits were sent to Chile for experimental work. This equipment arrived about January 1 when work was started. As the nitrate producers, due to old established customs, insisted on large-diameter holes, it first was attempted to drill 6-in. holes.

through soft broken material by rotating the steel only. The bit could be extracted readily when it became time to change from one length to another.

After considerable experimental work a trial was made under working conditions, with the following results: The operator connected his machine to the air-line and proceeded to drill five holes, 9 ft. apart, at the points spotted by the superintendent of Rajos. These five holes were drilled in 5 hours and 15 minutes, making a total of 53½ ft. The time included setting-up and moving from one hole to another. The cost, including labor, power, and lubrication, was \$2.01 Chilean currency, as compared to \$3.97 per foot drilled by hand.

This represented the necessary drilling for the breaking of approximately 5000 cu. ft. of material, as compared to 1000 per hole drilled by hand. While the difference in cost is encouraging, that is not the most important item to be taken into consideration by the American manufacturer or the nitrate producers themselves. The point of interest to both is that this shows a large increase in material produced per man.

The question of blasting was also studied. It is a simple

Mining Nitrate in Chile

This was a failure for many reasons. The large bits that were tried lost gauge quickly, due to the heating in dry drilling, and the excessive friction caused by rotating in a large circle. Also, the larger the hole the more susceptible to caving; and most important of all, the larger the hole the more power was required, not so much to cut the rock as to keep the hole clean of cuttings. For example, in drilling a hole 6 in. diam. at the rate of 5 in. per minute, there is about 400 cu. in. of loose cuttings to be expelled per minute in order to keep the hole clean.

Different types of detachable bits were tried, as a detachable bit is particularly desirable, due to the fact that the work generally is some distance from the blacksmith-shop. It is interesting to note that the best results were derived from the old cross-bit, commonly used in mining all over the world. The size of bits finally adopted was 3¼-in. starters, finishing with 2¾-in. at a depth of 9 ft. The Turbro drill in its construction had a great advantage due to its independent rotation. On several occasions the drill went

shallow-quarrying problem, in fact the loading of the holes with smooth walls properly tamped, using a booster in form of a cartridge consisting of a stick of 62% dynamite, 3 by ½ in. and a No. 6 cap, gave as good results as hand-drilled holes loaded as shown. This plan also lends itself to simultaneous blasting with a battery, which had never been used before. It was not customary even to put a cap on the end of the fuse in the old method of working.

The object of shooting in front of any apparatus for moving dirt mechanically is to loosen it. A certain proportion of the material is left in the form of boulders. These were block-holed by using a small drill made by the same manufacturer, known as the Clipper. The cutting speed and portability of this machine can be appreciated from a trial run which gave twelve holes per hour at an average depth of 12 in. per hole.

Bulletin LD-101, issued by the Edison Lamp Works, discusses maintenance of lighting systems.

More Tons Per Dollar

This is the basis of Massco Service—and you'll find it holds true whether you purchase Massco "Alpha" brand conveyor belting, transmission belting; Massco steam, air or water hose; Massco packing or pump valves, and any of our other mechanical rubber goods or industrial plant equipment—**greater tonnage output per dollar invested.**

Massco Mechanical Rubber Goods are manufactured under specifications which guarantee service; they are branded with our trademark and we stand squarely back of every shipment.

First and last, every item in the Massco Mechanical Rubber Goodsline represents quality coupled with top-notch value.

Massco engineers are ready to help you with your plant equipment problems. They know mining needs and you can safely put your troubles up to them.

Well stocked warehouses assure prompt deliveries, especially on emergency orders. Send your inquiries direct to the Massco Office nearest you.

Send for Bulletin 60—shown above. It covers the entire line of Massco Mechanical Rubber Goods. It should be within your reach. Send for it today.

T. A. RICKARD, Editor

DR. VON SIMMONS, the Secretary for Foreign Affairs at Berlin, said, at the opening of the National Assembly: "German-American official relations will not be changed before March 1921." Perhaps. Meanwhile in England it has been announced that by Order in Council the date of the termination of the war with Germany was fixed as January 10, 1920. The Armistice was signed on November 11, 1918!

IN the latest issue of our New York contemporary we note a letter, signed 'X', on the subject of metal quotations. The writer of this letter says: "From the standpoint of the trade I therefore consider that the 'Journal' is the best-fitted agency to determine the average price of lead." This might be interesting if the writer had signed his name instead of hiding as an unknown. The editor might have insisted upon a proper signature to this letter instead of interjecting a foot-note about "mud-slinging editors", which is merely a childish expression of spleen. The opinion of Mr. X that the 'Journal' is best fitted to quote accurate average prices for lead, or for other metals, is unimportant as against the recent confession of the editor of the 'Journal' that he cannot give accurate quotations, and that he would like to delegate the task to Mr. X or Mr. Y.

CALIFORNIA ranks first among the States in the variety of mineral substances that are produced on a commercial scale, and except for four Eastern States, where iron and coal are mined in great quantity, it leads in the gross value of mineral production. For 1919 this amounted to \$196,473,560, according to statistics recently prepared by the State Mining Bureau. Fifty different substances, of which eleven, in the crude form, were valued at more than a million dollars each, are included in the list. California is the only State that produces borax, and it supplies three-quarters of the domestic output of mercury. It leads in gold and platinum; it competes with Colorado for first place as regards tungsten and with Oklahoma in its production of petroleum. Crude-oil is by long odds the most valuable product, 101,182,962 barrels, worth \$142,610,563, having been mined in 1919. Gold takes second place, the value being \$17,335,100. Less than 3000 tons of coal and only 2300 tons of iron were mined. There was a marked reduction in the output of most of the metals as compared with

1918. The production of copper decreased to less than half, of lead and tungsten to approximately one-tenth, while the value of manganese fell from almost a million to \$450,000. Quicksilver diminished one-third in quantity and one-half in value, but even then was worth \$1,353,381.

ANNUAL reports of mining companies usually give the names of the president, vice-president, and directors; they also state the names of the secretary, treasurer, and so forth, but they omit sometimes to record the man upon whom, more than any other, the success of the enterprise depends—the manager at the mine. We have received the annual report of the Howe Sound Company, for example. The names of various important and unimportant persons appear in handsome print on expensive paper, together with a statement to the shareholders signed by the president of the company. Nowhere, not even in the president's report, is there any mention of the manager or of any member of the technical staff. The Howe Sound Company owns the Britannia, one of the finest copper mines in the world and a highly technical undertaking, as we happen to know well, because we have been there. One would suppose from the report that the assistant-secretary and assistant-treasurer were more essential to the prosperity of a mine and mill than the superintendent of either one or the other. If the shareholders are wise they will show some reasonable curiosity in regard to the personnel of the staff at the vital spot as well as in the office at New York.

THOSE of us with an abiding faith in the proposition that 'nothing is, that is not useful', especially if we happen to have supersensitive olfactory nerves, may find consolation in some experiments conducted by the Bureau of Mines whereby the malodorous properties of certain substances are put to practical use. Various schemes have been tried for warning miners in remote mine-workings of fire or other danger; the difficulties are obvious. The tests made by the Bureau in the Speculator mine at Butte, and in the North Star and Empire mines at Grass Valley, California, demonstrated that a signal could be transmitted a distance of as much as a mile in less than five minutes by introducing certain chemicals into the pipes conveying compressed air to the working-places. A pungent gas is formed that mixes with the

compressed air and circulates with it to the most remote parts of the mine. To be suitable the gas that makes the stench should be harmless; it should not irritate the eyes, for fear of hindering the miner from finding his way; it should have a high vapor-pressure, to permeate widely; and, lastly, it should be disagreeable as well as distinctive, so as to compel attention. Butyl mercaptan, ethyl mercaptan, and amyl acetate are, in order, the most satisfactory substances. The last is artificial banana-oil and is rather pleasant, which, according to the Bureau engineers, is not in its favor.

ON his return from Scotland, Dr. Victor C. Alderson, president of the Colorado School of Mines, made sundry interesting remarks on the oil-shale industry. The Scottish shale, he says, yields 20 barrels of oil per ton, this being half the yield from American shale. Even at that the Scottish shale affords a net profit of 50 cents per ton, despite the fact that the mining is done by hand and that wages are about \$4.50 per day. The retort used in Scotland is not suited to our Western shale; out of 14 types of retorts only one is at all adapted to the beneficiation of the shale deposits in Colorado, Utah, and Wyoming. Dr. Alderson states further that crude oil can be won from shale at \$1.85 per barrel in Colorado and Utah, where 5500 square miles of such rock is available for exploitation. A yield of even one barrel of oil per ton of shale represents a fabulous output. One 10-foot bed of shale, at one barrel per ton, represents over fifteen million barrels of oil per square mile of shale. The production of petroleum from wells in this country to date has been obtained from 4109 square miles, the estimated yield having been 2,280,000 barrels of oil per square mile. These are big figures. We hope that Dr. Alderson will succeed in stimulating intelligent interest in the subject. We note that the Comptroller of the Currency speaks of "the limitless oil-shales of the West" in context with our resources in water-power.

DEFLATION of prices is in progress, as most of us have begun to discover, not without satisfaction if it concerns the things we buy, and not without chagrin if it concerns the things we sell. The Federal Reserve banks are using gentle but effective means for restraining further gambling in merchandise; and some people have become sadder and wiser, while others have become more cheerful, but no wiser. Mr. John S. Williams, Comptroller of the Currency, says: "The deflation and subsidence in prices is proceeding by orderly and satisfactory steps and methods." Deflation usually involves some crinkling, and subsidence some cracking, but the operation, like that of the surgeon, is highly satisfactory even if the patient feels somewhat piano for a time. The slowness of the process, we are told by the knowing ones, gives the best evidence that it will proceed safely. It is over-due, but we trust this will not intensify the unpleasant symptoms, such as are recorded in the list of bankruptcies. One splendid feature of this economic crisis, impending ever since the Armistice, is the strong posi-

tion of the banks, National and State, as shown by Mr. Williams in his recent address before the Maine Bankers Association. To the establishment of the Federal Reserve system our entire economic structure is greatly indebted for moral, as well as financial, support. Thanks in large measure to it, as Mr. Williams says, "we have the right to look to the future with confident hope".

ACCORDING to news in the latest Australian mail the leaders of the strike at Broken Hill profess their belief that an early settlement is possible. This was a month ago, however, and as yet the cables have not apprised us that work has been resumed. The strike, which began in May 1919, is one of the most protracted and bitterly waged industrial disputes on record. While only about 2500 miners are directly concerned, their refusal to work has affected more than 20,000 employees, whose income has been largely stopped for fifteen consecutive months. In spite of widespread suffering, which we are told entailed actual starvation, the men have refused stubbornly to accept the terms offered by the employers. The demands include a six-hour day, a five-day week, the abolition of both the contract system and night work in the mines, and a minimum wage of £1 per day. With respect to the contract system of payment, we believe the miners are in the wrong; likewise we fail to see reasonable grounds for insisting on a five-day week. The workmen point to the extremely large dividends that were paid during the period of the War, and decline to believe the contention of the companies that they would be unable to operate at a profit under the conditions for which they are striking. Just what concessions the employers are prepared to make we do not know, but there should be a basis on which both sides could see their way to a resumption of an industry that heretofore has produced silver, lead, and zinc to the value of five or six million pounds sterling annually.

A SUBSCRIBER writes asking for a list of "the six largest mines in the world, that is, those mining and milling the largest tonnage, in the year 1917". This has incited us to delve into some statistics, with sundry interesting results. The eleven companies that mined the greatest amount of ore during 1917 are, in their order, Utah Copper, Anaconda, Nevada Consolidated, Inspiration, Chino, Ray, Calumet & Hecla, Chile Copper, Alaska Gold, Crown Mines, and Randfontein Central, the last two in South Africa. The iron-mining companies are not included in the comparison, although it may be mentioned that the Oliver Mining Company, from its group of properties in Michigan and Minnesota, mines 25,000,000 tons in the course of a year. Perhaps our seeker after information will object to the inclusion of Utah Copper on the ground that its steam-shovel operations make it a quarry rather than a mine, more like the pits of the iron ranges than his notion of a hole in the ground from which ore is hoisted. Other mines of the disseminated copper group belong to the same category, but the word 'mine' is not limited by any such restriction. A

mine is an excavation in the earth from which mineral is removed. An oil-well, a salt cavern, a sulphur bore, a glory-hole, an open-cut for hydraulic operations, a series of terraces for steam-shoveling are different in kind but they are all veritable mines. Our inquirer may even demur to the classification of the Anaconda as a unit because of the fact that the company actually operates a score of mines at Butte, although one can descend the High Ore shaft at the northern end of the district and emerge from the Original in the heart of the city after having traveled through workings wholly within Anaconda ground. However, a mine is not limited to one shaft or to one claim; it is a unit if it belongs to a single proprietary. Probably, however, the single shaft through which the most copper ore is hoisted is that of the Inspiration. We give herewith the record of tonnage in 1917 for several groups of mines:

Disseminated Copper

Utah Copper	12,542,000
Nevada Consolidated	4,064,000
Inspiration	3,891,000
Chino	3,608,000
Ray	3,560,900
Chile Copper	2,904,000
Braden	1,750,000
Miami	1,640,000

Michigan Copper

Calumet & Hecla	3,159,000
Quincy	1,280,000
Ahmeek	1,271,000
Osceola	1,237,000

Other Copper

Anaconda	4,300,000
Copper Queen	1,277,000

South African Gold

Crown Mines	2,100,000
Randfontein Central	2,017,181
East Rand Proprietary	1,700,000

Miscellaneous

Alaska Gold	2,240,346
Homestake	1,677,623
Rio Tinto (1913)	1,859,571

The Polish Muddle

The impression prevails that Poland tried to get a home-run on a foul. Nobody could have dreamed three years ago that the painful work of reconstruction after the War would be imperiled by fighting between Russia and Poland. At that time Poland was crushed to earth and Russia was in the hands of madmen. One of the first fruits of the Treaty of Versailles was the restoration of Poland as a nation and the fixing of boundaries that gave the Poles the territory to which they were entitled ethnically, in accord with the ideas of national self-determination that were awakened during the great struggle with Prussian piracy. The countrymen of Kosciusko and Paderewski wanted more, they aimed to restore the vague outlines of the Polish kingdom of 1772, but their importunities had to give way to the greater need for establishing a European peace. Most of us were sympathetic, the American Relief organization gave prompt aid to the hungry, and one of Mr. Hoover's best stories was the one

in which he told of the 45,000 barefooted children at Warsaw that passed in review before him in order to express their gratitude. Meanwhile there was talk of Poland becoming a buffer against Bolshevik incursion and of serving as an obstacle to German exploitation of Russia. The Germans and the Bolsheviks were the bogies of civilization; anything that would circumvent them was well worth while. Germany had her revolutions and counter-revolutions. Interest was diverted from Warsaw to Berlin. Then in May of this year we began to hear about the Polish campaign in Russia, Poland was on the aggressive, a strong army had been mobilized and was about to seize the Ukraine. It might be a crime, but it was being done against the criminal Soviet republic, and that made it almost respectable. So there was but little protest. The government of Lenin and Trotzky was about to collapse in any event and the Ukraine would be happier under Paderewski, of Pilsudski, or whoever was in control at Warsaw, than under the bloody tyrants at Petrograd. Here we may refer to the fact that of all the subjects that have been darkened by misinformation there has been none so obscured as Russian affairs during the last five years. The columns of the great newspapers of London and New York, for example, have reeked with rot; there have been enough silly books written on Russia by ignorant reporters and stray litterateurs to fill a library; the telegraphic dispatches from "our own correspondent" have been ludicrous in their contradictions. One reason is that few people know the Russian language; another is that prejudice for or against the Bolshevik regime has stupefied the judgment of those who have written on Russian affairs. For ourselves, we believe that outlaws to civilization are in the saddle at Petrograd and that the welfare of the world will be furthered by making an end of them; nevertheless, that does not excuse Polish invasion, which was prompted by territorial greed. The Poles having failed in their banditry, now play the baby and make an appeal "to the conscience of the nations"; they are screaming that the fall of Poland will be "due to the indifference of a world which calls itself democratic". This is shameless effrontery. The Polish Counsel of National Defence, from whose proclamation we quote, also says that "Bolshevist victory on the Vistula threatens all Western Europe". It may be true, and the probable truth of it introduces a complication of which the Poles and their friends are making the most. Of course, the Bolsheviks intend to organize a Soviet at Warsaw; and that in turn will serve as a new outpost for Bolshevik propaganda in Germany. The menace is plain.

At the critical moment, on August 10, our government through the Secretary of State, Mr. Bainbridge Colby, in a note to the Italian ambassador at Washington, stated the policy of the United States in unequivocal terms. The hope is expressed that an armistice may be arranged and the territorial integrity of both Poland and Russia respected, but "this country strongly recoils from the recognition of the Bolshevik regime". The government and people of the United States desire to help the Russian people and are unwilling that while "in the grip of

a non-representative government, whose only sanction is brute force, Russia should be weakened still further by a policy of dismemberment, conceived in other than Russian interests". The whole pronouncement, as made by Mr. Colby, is strong and sane. It has decided moral value, even if "the employment of all available means to render it effectual" prove, under the circumstances, only an academic phrase. It is extremely unlikely that the government of the United States will be willing to use either naval or military force to assist Poland at this time. On the same day, Mr. Lloyd George, speaking for England, said that the Polish attack on Russia was not justified and that it was made despite the warnings of the Allies, but that "nothing justifies retaliation, reprisal, or punishment which goes to the extent of wiping out national existence". In other words, the independence of Poland must be preserved, because "its existence as an independent nation is an essential part of the structure of European peace". He himself had been negotiating with Mr. Leonid Krassin, an emissary of the Soviet government of Russia, whereas the French government allowed it to be known on August 12 that it had already agreed to support General Wrangel, who has set up a military government in the Crimea and is battling with the Bolsheviks. The reason given by Mr. Millerand, the French premier, is the traditional friendship between France and Russia, whereas the reason given by rumor is the undertaking of General Wrangel to recognize the debts incurred by Russia to France during the Czarist regime. It is a pretty mess. The complexity of the muddle is increased by the fact that the Russian armies are commanded by officers of the old Czarist army and by many of those who served under the Kaiser, whereas the Polish armies include numbers of Frenchmen, Britons, and even some Americans. The Great War of 1914-1918 has been followed by a hideous nightmare in which brave soldiers from the various armies find themselves fighting under unaccountable alignments. One thing is clear: the Polish attack has aroused the national spirit of the Russians and rallied them for the moment under the leadership of Trotzky, *alias* Braunstein, a German Jew, and Lenin, *alias* Ulianof, a Kalmuck. The Czarist officers answered the national call and the young men have enlisted in the army largely because military service ensures them better food and clothing than the civilian population can obtain. The Poles, instead of checking Bolshevism, drove the Russian people to the support of the Bolshevik regime. Instead of serving as a rampart against the savagery of the anarchist, Poland has become an excuse for a further onslaught upon Western civilization. That menace outweighs the plight of Poland, much as we may deplore it. If Bolshevism overwhelms Poland, it will inundate Germany. Civilization is on the defensive. The best way to kill Bolshevism is to let the Russians stew in their own juice; if they come beyond their own borders they must be driven back, but to invade Russia is to strengthen the Bolshevik regime, which would have collapsed ere now if foreign interference had not rallied national sentiment to its defence.

Federal Trade Commission and Minerals Separation

In this issue we publish the record of the testimony given by the editor of this paper before the Federal Trade Commission, which is hearing a complaint against the Minerals Separation companies. We have omitted some of the irrelevancies and immaterialities, and corrected some obvious errors in the reporting of the colloquies between the witness and counsel, but we believe these minor omissions and changes will meet with the approval of counsel on both sides. The Minerals Separation people were given an opportunity to expose the shady past of the witness and to prove the sinister influences that have controlled his public criticism of their doings. They did their best and failed utterly, of course, because there was nothing to uncover. A petty fuss was made over an editorial that appeared in the 'Mining Magazine' of May 1912. That editorial was rather friendly, than otherwise, to the Minerals Separation people, so Mr. Nutter challenged the editor of the 'Mining and Scientific Press' to re-print it, on the supposition that the editor of the 'Press' had written the editorial in the 'Magazine', and therefore had exhibited gross inconsistency as between his attitude in 1912 and in 1917. As the testimony shows, the editorial of 1912 was written by Mr. Edward Walker, assistant to the editor of the 'Mining Magazine', not the editor himself. At that time the interest in flotation affairs was small, the process was relatively unimportant, the mining profession had but little curiosity concerning it, and had heard of it chiefly through the story of the miserable quarrel between the Elmore brothers and the firm of Sulman & Picard. Sundry points in patent law had arisen and sundry litigations were in progress, but they were not deemed in any sense vital to the mining industry. Mr. Walker, a resident of London, had given some attention to the subject previously and to him naturally was delegated the writing of the editorial upon the organization of an American branch of the Minerals Separation company. We reproduce Mr. Walker's article on page 279. Naturally no reason existed for the re-publication in the 'Mining and Scientific Press' of an article in another paper written by a gentleman in no way connected with the 'Mining and Scientific Press'. We have omitted the interrogatory concerning a correspondence between the witness and Mr. Ballot, because it has no significance, except to show that they could exchange letters politely, and that, although the witness consistently opposed the exactions of Minerals Separation, he was still on such terms with the chairman of the company as showed that there was no personal animus and no underground motive for his criticism. The record of this small part of the proceedings suggests how much time is lost in aimless questioning, it being evident that counsel for the Commission did not know what testimony the witness could give that bore upon the complaint, and was engaged chiefly in a fishing expedition. It remains to extend our compliments to counsel for the respondents and express the regret that the clever lawyer is so often on the wrong side.

Minerals Separation Before the Federal Trade Commission

Excerpt From the Record of Proceedings

THOMAS ARTHUR RICKARD was thereupon called as a witness, and, having been duly sworn, testified as follows:*

DIRECT EXAMINATION

By MR. HAWKINS:

Q. Will you please state your name, Mr. Rickard?

A. Thomas Arthur Rickard.

Q. And where do you live, Mr. Rickard?

A. Berkeley, California.

Q. What business are you engaged in?

A. Editor.

Q. What are you editor of?

A. The 'Mining and Scientific Press'.

Q. What is that?

A. It is a professional weekly publication—[spelling it] w-e-e-k-l-y.

Q. To what extent is it circulated, where is it circulated?

A. It circulates as widely as it can, and that is around the world.

Q. Does it circulate to any particular class of people?

A. It circulates among those engaged in mining and metallurgy.

Q. What has been your engineering education, if any, Mr. Rickard?

A. I am the son and grandson and great-grandson of a mining engineer. I was graduated from the Royal School of Mines in London in '85, when I came to Colorado, and there I was engaged as an assayer, surveyor, mine manager, and consulting engineer, successively.

Q. In 1905?

A. In 1885. I was State Geologist for Colorado for three terms, under three different Governors.

Q. Are you the author of any books, text-books, or books on mining engineering?

A. Yes, seven or eight books.

Q. What are they?

A. 'The Stamp Milling of Gold Ores', 'Pyrite Smelting', 'The Copper Mines of Lake Superior', 'Journeys of Observation', 'Through the Yukon and Alaska', 'Flotation', 'The Flotation Process'. There are others, the names of which I don't recall for the moment.

Q. What has been your experience with flotation and the flotation process?

A. I am familiar with it in a general way, and I have

read what others have written. I have visited a number of mills where it is in use, I have watched it in operation, I have made minor experiments on my own account in order to try to understand the physics of it, but I am not a specialist or an expert; I am an editor.

Q. Have you made any study of it other than you describe?

A. I have made a study of it for the purpose of understanding the litigation, the processes, and the writings of other people.

Q. Now, in your study of it what sources of information have you used?

A. I have gone to those who were directing flotation operations, I have gone to specialists and have asked them for light on the obscure phases of the subject. I have been to a large number of mills where it has been in use, and, as I have said, I have conducted some of the elementary experiments that are needed to understand the phenomena of surface-tension.

Q. Are you the author of any literature on flotation other than the books you have described, any articles?

A. Yes. I have written a number of articles by way of comment and criticism, as editor of the 'Mining and Scientific Press', and I may add, in order to win a smile from the very solemn face of Mr. Nutter, that in 1918 I was asked by the 'Encyclopedia Americana' to write the article on 'Flotation', and I took great pleasure in doing so. Now [beckoning to Mr. Nutter, who thereupon did smile]; thank you.

Q. What is your familiarity with the articles in mining magazines written by other authorities on the subject of flotation?

A. Well, I have published a great many of those articles myself, and I always revise carefully anything that I publish. I have also read articles written in other magazines by other people.

Q. You said you came to this country when?

A. In 1885.

Q. How did you become acquainted with Mr. Ballot?

A. I was editor of the 'Engineering and Mining Journal' in 1903, and then I came here and obtained the control of the 'Mining and Scientific Press' in 1905, because I wanted to be an independent editor, and I didn't have enough money to buy the 'Mining Journal', but I did have enough to buy the control of the 'Press'. In 1909, on the invitation of a number of mining engineers, some of them Americans, I went to London to start 'The Mining Magazine', and while there I made the acquaintance of the principals in Minerals Separation: Mr. Sulman and Mr. Picard, who were among the leading mem-

*The Commissioner and presiding officer is Houston Thompson. G. R. Hawkins and Claude R. Porter are attorneys for the Federal Trade Commission. Alfred A. Cook is counsel for the respondents, the various Minerals Separation companies.

bers of the profession. Mr. Curle, one of the directors, was one of my very best friends, and he is still—I believe I am not his, but he is mine—and I also made the acquaintance of Mr. Ballot, through Mr. Curle.

Q. Are you acquainted with their policy, or were you at that time, with reference to the restriction of the dissemination of knowledge with reference to the art of flotation?

MR. COOK: That is objected to as irrelevant and immaterial.

COMMISSIONER THOMPSON: Whose knowledge? You don't say in your question.

BY MR. HAWKINS:

Q. Were you familiar with their license agreement, of the Minerals Separation?

A. I was not then. Not when I was in London. I have become so since.

Q. Are you familiar with it now?

A. I have seen copies of it since then.

Q. I hand you a copy of Exhibit 46-L, which is a copy of the license agreement, and call your attention to clause 9 of the last sentence. Now, will you tell us whether during the time you were in London, the Minerals Separation Company had a clause of that character in their license agreement?

A. I was not aware of it, but I was aware of the extreme paucity of information available concerning the technology of the process.

MR. COOK: I move to strike that out as not responsive.

COMMISSIONER THOMPSON: We will let it go in.

BY MR. HAWKINS:

Q. What did you inquire for?

A. I inquired for information that I thought would be of benefit to those who would be likely to use the process.

Q. What did you want the information for, for personal use, or to publish?

A. To publish in 'The Mining Magazine', of which I was then editor.

Q. You spoke regarding Mr. Hoover's book.

A. Yes.

Q. It was published by 'The Mining Magazine'?

A. The Mining Publications Company; that was the holding company. We published the book for Mr. Hoover.

Q. What year was it that you published Mr. Hoover's book?

A. The book was published in 1912.

Q. Did you ever have any talk with any of the officials of the Minerals Separation with reference to its publication?

A. Yes. When Mr. Hoover offered me the manuscript of his book, I realized it was a book for which there would be a big demand. I knew he was extremely well fitted to write such a book at that time. Therefore I was very glad to get it. When I looked through his manuscript, I found certain parts that seemed to me not suitable for publication, especially the chapter that dealt with patents. I submitted to Mr. Hoover that he should not publish this part of the book.

MR. COOK: I object to the conversation between Mr. Hoover and the witness. He was not in the employ of the Minerals Separation.

COMMISSIONER THOMPSON: Sustained.

BY MR. HAWKINS:

Q. State what your conversation with the Minerals Separation people was.

MR. COOK: I object unless the particular person or persons of the Minerals Separation Limited with whom Mr. Rickard had talked are mentioned.

COMMISSIONER THOMPSON: You can name the persons in the Minerals Separation, the names of the persons with whom you discussed the matter, and then you can state what you discussed.

A. John Ballot and J. H. Curle.

BY MR. HAWKINS:

Q. What was said at that time, at that conversation, by you and by them?

A. Having made up my mind that the book could not be published without the consent of these gentlemen—

MR. COOK: I move to strike that statement out of the mental operation of the witness.

COMMISSIONER THOMPSON: The witness may proceed.

MR. COOK: Exception.

A. (continued). I told Mr. Hoover I would not be a party to the publication of the book without the consent of his former employers, but that I would try to get their consent.

BY MR. HAWKINS:

Q. Why was it necessary for you to get the consent of Mr. Ballot and Mr. Curle?

A. Because I knew that Mr. Hoover had been in their employ, and I thought it was the proper thing for him, as a professional man, to get their consent; otherwise he would lay himself open to the charge of disloyalty that had already been made against him in *ex parte* proceedings. So I went to see Mr. Ballot and Mr. Curle and pointed out to them that if they would be reasonable, if they would give their consent, Mr. Hoover would probably delete parts of the book that should not be published, and if they were unreasonable he would probably publish it elsewhere; that I would not myself publish it unless they gave their consent. I advised them in the most friendly way to be reasonable, otherwise they might have a great disservice done to them; and so it was arranged that the manuscript of the book should be submitted to their patent lawyer—I think he was called Ballantyne—and Mr. Hoover acted most frankly in the matter and agreed that this inspection should be made. The manuscript was sent to New York, to Dr. Gregory, I was told, and they had a cat-and-dog time of it for three or four months—

Q. A cat-and-dog time—what happened, if you know?

MR. COOK: Were you present when they had this cat-and-dog time?

A. I was present at echoes of it, in conversations. What we did finally was to accept the manuscript, with many alterations and corrections in red ink, which

marked the exceptions taken by the experts of the Minerals Separation to portions of the text. Those corrections were all accepted in good faith by Mr. Hoover, and by me, as publisher, and the book was forthwith published.

By MR. HAWKINS:

Q. Do you know of any other instances in which they have censored publications on flotation?

A. Yes, most assuredly, in my own case.

Q. Tell us of that.

A. In 1915, returning here, I saw the importance of the subject and undertook to publish matter on flotation. Among others I went to see Mr. Charles Butters at Oakland.

Q. Who is he?

A. Mr. Butters is a well-known mining engineer, a metallurgist of high standing, and a man of international reputation. I went to see him because he was an old friend of mine and because he had a laboratory in which a Minerals Separation machine was in operation. I was curious to learn all I could about the process, and I decided that a good way of eliciting information for public use would be to interview him. He consented to be interviewed; this was in July 1915. He gave some interesting information concerning his own experiments. Soon afterward Mr. Nutter came to my office and asked me whether I had some such article or interview in preparation for publication, and I acknowledged at once that I had.

Q. What was the character of this information that you were going to publish?

A. Well, the interview itself concerned Mr. Butters' past experience in metallurgy, and gave his opinion as to the importance of flotation at that time, and as to its applicability to various ores. So Mr. Nutter came to me—I had known him in the most pleasant way for many years—and he asked me whether I had this article. I said "Yes"; so then he said, "I have got to raise a red flag"—a curious phrase—I knew the meaning of it, of course. I said to him, "Excuse me for a moment if I do not answer, because I am angry." So I waited for an interval, and then asked him "You undertake to warn me not to publish this article?" He said, "Yes." I said, "Why?" He said, "Because Butters is a licensee of ours, and he has no right to give the information, and it may interfere with our business." Thereupon I answered, "This article is the property of the 'Mining and Scientific Press'. It is in my drawer here, and no man alive has a right to come to me and tell me not to publish it—not even Mr. Butters. As a matter of courtesy to Mr. Butters, if he asked me not to publish it and gave a valid reason, I should probably acquiesce, as a matter of courtesy, but I have worked on this thing as much as he has, and it is the property of the 'Mining and Scientific Press'." Then I added, in a not unpleasant way, "You have no more right to butt into this than a man in the street. This is going to lead to a great deal of unpleasantness if you press the matter." I think I volunteered to give him the text of the article. At all events, I did give it to him, and I said, "You may take it with you;

there is no great hurry about the publication of it," and I think he asked if he could send it to Dr. Gregory—I know he did send it to Dr. Gregory, because he told me so, and then again I told him that I hoped he would not insist on objecting, because I did not want to have a row with him personally. Mr. Frank H. Probert, Professor of Mining in the University of California, was present at the conversation.

In due course—it may have been ten days later—Mr. Nutter notified me by telephone that he had heard from Dr. Gregory, and that Dr. Gregory was not unwilling to have the article published, but that he himself was still unwilling to give his consent. Whereupon I told him I would come down to his office—if I recall correctly, my office was in course of repair, whitewashing or something—so I went to his office. He repeated to me what he had said over the telephone, and I said to him, "What is it that you object to?" "Well," he said, "for instance, what Butters says about treatment of the concentrate by chloridizing-roasting and leaching with cyanide. I am thinking of taking out a combination patent for that myself." "Well," I exclaimed, "Good Lord! That is a thing that any metallurgist would try. It is a thing I tried in 1892." I thought it a most extraordinary objection that the article should be withheld because a most obvious suggestion made by Mr. Butters was one that Mr. Nutter himself proposed to patent, and thereby prevent others from using; nothing new, but simply an idea that had been used at least 28 years before—had been used by myself in Arizona, 28 years ago. Again I asked him not to persist in his course, and urged him to refer the matter again to Dr. Gregory; or it may be that he agreed, without my urging, that he would submit it again to Dr. Gregory. He did submit it again to Dr. Gregory, and a few days later I received a telephone message from Mr. Nutter releasing the article for publication. I said, "Any changes?" He said, "No, it is not worth while," or something of the kind, and the article was published in our issue of August 21, 1915.

Q. Have you had any other experience of a like character?

A. No, because no attempt has ever been made against me since then to curb my proper function as an editor.

Q. What would you say as to the importance of flotation in metallurgy?

A. Well, I heard the question asked this morning, and—

Q. What do you have to say?

A. (continued)—and I at once framed an answer in my own mind, as I heard it asked then: Flotation is one of the most remarkable methods of ore reduction that has been devised by man; but, of course, this does not apply to the one method, but to the many different methods of doing it.

Q. What would you say as to the need of free exchange of information in the development of flotation?

A. Absolutely vital to the welfare of the industry.

Q. Why?

A. Because the progress of individuals is only made

by learning from the efforts of others. No one man ever applied a process successfully on his own experience.

Q. Are you acquainted—I think you said you were acquainted with the license agreement of the Minerals Separation North American Corporation?

A. Yes.

Q. You are acquainted with Clause Nine, which I have shown you?

A. Yes.

Q. The last sentence of which reads: "The licensee shall not, without obtaining the consent of the licensor, communicate any details connected with the work of any of said inventions, modifications, conditions, or improvements to any third party." What would you say the effect of that has been upon the advancement of flotation?

MR. COOK: I object to that as problematic and speculative.

COMMISSIONER THOMPSON: I think that question is too general.

MR. COOK: Indefinite.

COMMISSIONER THOMPSON: And indefinite.

THE WITNESS: Mr. Commissioner, may I ask a question?

COMMISSIONER THOMPSON: You may.

THE WITNESS: In order to get at the whole truth—I am a witness—I think this is the first time I have ever been a witness—am I not to give information that is not asked me in questions? It seems to me in order to get the whole truth—counsel is endeavoring to elicit the truth, but his inquiries do not always throw the light—is it not within my province to tell it?

COMMISSIONER THOMPSON: You are supposed to be interrogated by counsel, and he will take charge of that part of the case.

THE WITNESS: All right.

BY MR. HAWKINS:

Q. From your experience, Mr. Rickard, and your knowledge of flotation, which you have described to us, what would you say as to the advancement of the art in this country?

MR. COOK: I object to the question as indefinite and general.

BY MR. HAWKINS:

Q. Has it been fast or slow?

MR. COOK: I object to that as calling for a conclusion.

COMMISSIONER THOMPSON: I think he may answer.

A. It has been extremely slow, considering the importance of it.

BY MR. HAWKINS:

Q. What has made it slow? Or what has retarded it?

MR. COOK: I object to that.

COMMISSIONER THOMPSON: If he knows.

MR. COOK: And as indefinite and calling for a conclusion of the witness; as incompetent, irrelevant, and immaterial, in no wise binding on these respondents, nor the respondents represented. Exception.

A. I think I do know, and I shall be glad to state. The progress of the art in this country has been retarded

by the attempt to impose secrecy upon the experiments and the operations of those using the process, by means, of course, of these license agreements and other methods, but more particularly by the effort to tie individual metallurgists to the chariot-wheels of this patent-exploiting agency, by preventing them from giving information such as comes to—

MR. COOK: I move to strike it out.

COMMISSIONER THOMPSON: I think you are going too far when you speak of patent-exploiting agency. You may strike out that phrase.

A. Patent-owning corporations—we will call it Minerals Separation, for short.

MR. COOK: We won't call it Minerals Separation, for short.

BY MR. HAWKINS:

Q. What corporation do you refer to?

A. I believe I am testifying, sir; to the Minerals Separation, for short.

Q. When you say Minerals Separation, what corporation do you have reference to?

A. I mean the whole caboodle.

Q. You mean the Minerals Separation Companies or the Minerals Separation North American Corporation?

A. Both the one in London and the one in New York, as far as I know, are marked by the effort to bind technical men to secrecy, which is a matter that has greatly hindered the—

MR. COOK: Is there any question on the record? May I ask the stenographer to read the last question?

COMMISSIONER THOMPSON: The question is, what has retarded flotation?

MR. HAWKINS: Yes, he said that the advancement of the art had been held back, and I asked him what had retarded it, and he said he knew, and the objection of counsel came then. He said he knew, and he started to tell what had retarded the advancement of the art when the objection came, and as I understand it he had referred to the name of the corporation indirectly.

MR. COOK: Isn't that all speculative, whether there is any retardation or not?

MR. HAWKINS: No, here is a man—

THE WITNESS: As an example of the methods by which the art has been retarded, I cite a case that came to my notice, of E. M. Hamilton, who gave me a copy of an agreement or contract whereby a metallurgist in the employ of a licensee is estopped from giving any information to anybody, and he is bound to disclose anything he discovers in the course of his work to Minerals Separation. I published such an agreement in the 'Mining and Scientific Press', an agreement which was enforced and binding on Mr. Hamilton.

Q. Will you look into your files this evening or in the morning and find the publication of this contract?

A. Certainly, I will. So I looked at this agreement and it seemed to me to be extremely one-sided, and I advised Mr. Hamilton to take legal advice. I asked him if he would let me have a copy of the agreement and said I would submit it to a lawyer, because I was curious my-

self to know whether it was legal or not. I submitted it to a good lawyer, C. Irving Wright, and he advised me—

MR. COOK: I object to that.

COMMISSIONER THOMPSON: That is hearsay evidence, Mr. Rickard, unless you can produce—

A. I can produce the attorney's published statement, which was published in connection with the agreement, in my paper.

COMMISSIONER THOMPSON: You are not permitted to say what he said to you.

THE WITNESS: No, but he gave me his opinion, and he allowed me to publish it, and I published it, together with the copy of the agreement in Mr. Hamilton's name, and I told Mr. Hamilton, as I told other engineers, that I thought it was an iniquitous thing, and that it was peculiarly objectionable when it was entered into by an honorable man, because it tied him for the rest of his natural life—practically tied his hands as a metallurgist, because it made it extremely difficult for him to accept employment or a retainer from any other clients; while, on the other hand, Minerals Separation did not give the party to the contract anything in exchange for binding him.

MR. COOK: I object upon all grounds to what Mr. Rickard said to Mr. Hamilton, and I move to strike it out.

COMMISSIONER THOMPSON: Now, this is what he said in the discussion in his paper, I understand.

MR. HAWKINS: His opinion of the contract, what he thought was the iniquity of it, because it lacked consideration.

THE WITNESS: Certainly.

BY MR. HAWKINS:

Q. Have you any other instances of a similar character?

A. Yes, but not instances that I can recall sufficiently clearly to be worth relating here. I have had letters from time to time from people telling of their troubles. Mr. Jackson Pearce, for instance, told me some of his troubles.

Q. He told us that on the stand.

MR. COOK: I have here the article: February 5th, 1916. I think that is the publication.

THE WITNESS: Thank you. That is it.

BY MR. HAWKINS:

Q. Mr. Rickard, I have here the copy of your magazine under date of February 5, 1916, and on page 193 a copy of the agreement that you have just referred to in your testimony, which is the agreement with Mr. Hamilton, I understood you to say. As you have published here in your magazine, it was made with John Doe, and it appears that John Doe is a member of the staff of the Minerals Separation Syndicate, and that this form of contract here is one that was made with the members of their metallurgical staff. What do you know as to whether Mr. Hamilton, at the time he had this contract, or made it, at the time you refer to in your testimony, was or was not, a member of their metallurgical staff?

MR. COOK: Isn't Mr. Hamilton the best witness to testify to that?

MR. HAWKINS: I am asking him whether he knows.

Q. Have you any personal knowledge on the question?

A. No. It seems to be a question as to whether this contract was forced upon him as an employee of Minerals Separation or as an employee of Charles Butters. He gave me the information that it was a contract which had been forced upon him, and whether it was forced against him as one or the other, it was an objectionable contract on every account.

CROSS-EXAMINATION

BY MR. COOK:

Q. Mr. Rickard, I suppose this 'Mining and Scientific Press', of which you are editor, is sold, is it, by you to the public?

A. It is not given away.

Q. And the company that runs it, runs it for profit?

A. *Vous avez raison, vous êtes juste.*

Q. *Merci, Monsieur.*

REPORTER: I didn't get that.

THE WITNESS: You can put down, "A glimpse of the obvious," as Huxley said.

Q. Is Mr. Parke Channing a stockholder of your company?

A. Yes, sir, he holds \$5000 out of \$300,000; he is one out of 22 shareholders, and he is the largest shareholder outside myself; that is to say, no other shareholder has more than \$5000, and I personally own three-fourths.

Q. Do you know whether Mr. Channing has any affiliations as an engineer with the Utah Copper Company?

A. No, I don't know.

Q. You have no knowledge on that subject?

A. I would be surprised to find out that he had.

Q. Would you be surprised to find out that he was the consulting engineer of the Miami Copper Company?

A. I believe he is vice-president of the Miami Copper Company.

Q. Do you know Mr. Argall?

A. I do, indeed.

Q. Is he a stockholder of your company?

A. He owns \$5000, par value, which he has owned for 15 years.

Q. Do you know whether or not—

A. And the same applies to Mr. Channing; they both hold that small holding and have for 15 years.

Q. Do you know whether or not he has any control of the operations of the Argo mill in Colorado, at Idaho Springs?

A. No, I do not. That is news to me.

Q. And do you know whether or not he had anything to do with the installation of the flotation process at the Ozark mine in New Mexico?

A. Yes, I believe he had, because he told me so.

Q. You know, do you, that since 1911 to date, the Minerals Separation, Ltd., the Minerals Separation American Syndicate of 1913, Ltd., and Minerals Separation North American Corporation, are engaged in litigation in the United States courts with respect to their various matters?

A. Certainly.

Q. And you know that the litigation is being vigorously defended?

A. Defended as against them?

Q. Yes.

A. Not as vigorously as it ought to be, it seems to me.

Q. Not as vigorously as it ought to be?

A. No, not as effectively as it ought to be.

Q. But it is being defended vigorously and effectively?

A. I presume so.

Q. And that has been the situation constantly since 1911 in this country with reference to patents of Minerals Separation?

A. Yes.

Q. The case has gone up and down in various courts and been commented upon by you from time to time?

A. Yes.

Q. You say you were in London in 1909?

A. Yes.

Q. You are a native Englishman?

A. I am a native of Italy, but a man is not a horse because he is born in a stable. My father was a Cornishman.

Q. But a man may be always a gentleman?

A. Yes, sir, even under extremely difficult conditions.

Q. When did you become a naturalized citizen?

A. I am not yet naturalized: I have declared my intention.

Q. You are not an Englishman?

A. No, sir, I am not; I am an American.

Q. Do you recall a publication of yours in 'The Mining Magazine' when you were editor?

A. No, sir: I might recall one, but probably you are going to refer to a particular one.

Q. Do you know the one I want to refer to?

A. No, I have not the slightest idea.

Q. As editor, do you accept responsibility for publications in your magazine, of which you are editor?

A. I do.

Q. You were the editor of 'The Mining Magazine' in May 1911.

A. Yes.

Q. I show you an article on the subject of flotation processes, and ask you whether that was not published by 'The Mining Magazine' under your editorship?

A. I have no doubt that that is a correct facsimile.

Mr. Cook: I will ask to have it marked in evidence.

Q. Now, in your 'Mining and Scientific Press', when you came to San Francisco, you published a great many articles with reference to Minerals Separation, did you not, Mr. Rickard?

A. I did, yes.

Q. And Mr. Nutter wrote you a letter, did he not, calling to your attention this article that I have just read, and you declined to publish it later. Do you recall that?

A. No, I do not, but if he says so, I accept it. Yes, I do; I do recall his asking me, and didn't I give a reason?

Q. Yes, I am going to get the correspondence. Did you not receive under date of October 11, 1917, from Mr. Edward H. Nutter, chief engineer of the Minerals Separation North American Corporation, a letter of which I am handing you a copy, to which was attached a copy of the article that I just read in evidence?

A. Yes, I think that is so.

Q. That is the copy?

A. Yes.

Q. I show you what purports to be a copy of your reply, and ask you whether that is not a correct copy?

A. May I read it?

Q. Yes.

A. "Yours of the 1st inst. came duly to hand, and I have read it with interest. The editorial in 'The Mining Magazine' that you were kind enough to copy was not written by me, but by Mr. Walker. I can see no point in publishing it in our paper, but I shall always be glad to publish anything that you care to write." May I have my reply to Mr. Nutter in the record?

Mr. Cook: I am going to get it all in.

THE WITNESS: Because, you see, the suggestion is made that I wrote that editorial, and I didn't write it. Mr. Walker was my associate and assistant.

Q. You were editor of the paper that published it?

A. I was.

Q. And as you have stated in answer, you accept responsibility for everything published in your paper of which you are editor?

A. I simply wish to establish my personal consistency, that I did not write the editorial and could not have written it. At that time I took very little interest in the flotation quarrel, and I deputed that matter, which had mainly to deal with the litigation then going on in London, to Mr. Walker, who had been interested in it for some time previous to my coming to London.

Q. You received the letter from Mr. Nutter in reply to that, did you not, of which this is a copy (handing witness a letter)?

A. Well, that is merely a piece of maladroitness humor.

Mr. Cook: Well, we have had so much adroit humor from you—

Mr. Porter: I object to this. I don't think counsel has to indulge in such remarks as that.

COMMISSIONER THOMPSON: The witness did not answer the question.

THE WITNESS: Mr. Commissioner, I submit that the correspondence could not be understood by anybody reading the record, and they appreciate the fact.

COMMISSIONER THOMPSON: He asked you a question, and you have not responded to it, that was the point. You wrote the letter?

By Mr. Cook:

Q. You wrote the letter?

A. You asked me whether I received it.

Mr. Cook: The only point is, we offered this letter to Mr. Rickard for publication, and he declined to publish it for the reason he stated, and there was some personal correspondence between him and Mr. Nutter on the sub-

jeet, and the maladroitness humor, or otherwise, is not important in the case.

Q. Mr. Rickard, suppose you went to an inventor of a process and asked him to teach you and instruct you in the process, and its variations, and give you access to his plant, his laboratory, and acquaint you with the details of his business, do you think it important for that inventor to bind you to secrecy as to what you learned?

A. I would not go to him under those conditions.

Q. Please answer my question.

A. It is so supposititious.

Q. You would not go to him under such circumstances, but if you went to him under those circumstances?

A. If I went to him under those circumstances, I would refuse to sign any contract without a time limit. I probably would refuse to sign any contract of the kind to which you are now alluding.

Q. Well, you recognize the right, don't you, of the inventor to say, "Well, if you come to me and ask for instructions and ask for the secrets of my business, and all of the details of it"—to decline to give you that information unless you—

A. Well, he has a perfect right to decline to do anything.

Q. There is no obligation, is there, on the part of an inventor of a patented process to instruct another in the secrets or the details of it?

A. Yes, sir, but you have entirely overlooked the fact that I have denied from the beginning the invention by Minerals Separation. I don't believe that Minerals Separation invented the process of froth-agitation—I believe they only contributed to it.

Q. Mr. Rickard, irrespective of your own individual thought or view of the subject—

A. I can't disregard anything without respect to my own individual thought, sir. Why do you ask me such a foolish question?

Q. Well, it is a habit of mine not to be able to ask you any other kind of a question, I regret that. Unfortunately, I have not had the literary experience you have had.

THE WITNESS: It would have been useful.

MR. COOK: Yes, sir.

COMMISSIONER THOMPSON: Until counsel and the witness can get on a better basis, don't let us incur the record.

MR. COOK: I think the Commissioner will bear with me in saying that I am trying to get along with the witness.

By MR. COOK:

Q. Are the views that you have expressed today, as well as those that you have expressed from time to time in your publications, based upon the statement just given that you do not believe that they are the inventors?

A. I believe they were not the sole inventors of the froth-agitation process, but very important contributors to the development of the process.

Q. And I say the views you have expressed today, and from time to time—

A. Yes, sir.

Q. —are based upon the opinion you have given me?

A. Upon the belief.

THE WITNESS: Can I suggest a question, Mr. Commissioner, a question to the counsel that will elucidate—I have taken an oath to tell the truth and the whole truth—

COMMISSIONER THOMPSON: It is up to your counsel.

MR. HAWKINS: You mean me?

THE WITNESS: Yes, sir.

[The witness left the stand and said to Mr. Hawkins: "The question asked by counsel over there insinuates a sinister imputation; I want you to ask me when and how Mr. Argall and Mr. Channing became shareholders in the 'Mining and Scientific Press'." He then returned to the witness-chair].

MR. COOK: Mr. Rickard, I asked you as to the connection of Mr. Channing and Mr. Argall with your paper, and you told me of their interest. I did not mean to insinuate anything, but I simply wanted to ascertain whether they had a large or small interest in it. I had no thought of insinuation, Mr. Rickard, on the subject, and I think in fairness to you I ought to say and assure you that there is no insinuation whatever.

THE WITNESS: We will put the matter beyond any doubt.

By MR. HAWKINS:

Q. Is there any further explanation you wish to make with regard to the articles, or in regard to the subject of Mr. Argall or Mr. Channing?

A. Mr. Argall and I are personal friends. I knew him as a small boy. He was associated with my father. Parke Channing has been a personal friend of mine for nearly 30 years. Both of them were friends of mine long before the flotation issue appeared upon the horizon, and their holdings in the paper are very small. The only reason why there are any shareholders besides myself is because I wished to have the pleasant responsibility of having some small holdings by a number of representative engineers.

[Editorial comment on these proceedings will be found elsewhere in this issue. On page 279 we reproduce the editorial in 'The Mining Magazine' concerning which Mr. Nutter wrote.]

ELECTROLYTIC-ZINC works are now manufacturing spelter at Hobart in connection with the hydro-electric power scheme financed by the Tasmanian government. In addition to spelter, zinc sheets are being rolled, and it is proposed to extend the manufacture to the following: Lithopone blocks for marine boilers; zinc-shavings for the gold industry; zinc-dust for sherardizing metallic aluminum; ferro alloys; zinc alloys; zinc chloride; zinc sulphate; caustic soda; bleaching-powder; other chlorine products; and calcium carbide. The outlay of these works is estimated at £1,500,000, and the plant, which is now producing 70 tons of spelter per week, is being extended to produce 100 tons per day. In 1918 these works produced from New South Wales ore 3822 tons of spelter, at £152,880, and in 1919, 3668 tons, at £160,660.

Curves for Ore-Valuation

By K. K. HOOD

The estimating of tonnage in the ground and arriving at a value of that tonnage is far from an exact science. There is, however, often a certain amount of mathematical computation in which the same assumptions have to be made. These become burdensome because of their repeated application. In such cases charts or curves constructed from the desired data may be of assistance, and it was with this idea in view that the two curves shown herewith (Fig. 1 and 2) were constructed.

Fig. 1 shows a graph to be used in the computation of valuation of ore similar to that found in the Wisconsin zinc districts, where the minerals in the ore are a combination of zinc and iron sulphides in a proportion within the limits of the curve, and where the factors and resultants considered are (1) metallic zinc in the ore as indicated by sampling and assaying, (2) metallic iron in the ore, (3) grade of recoverable ore, (4) grade of concentrate produced, (5) the ratio of concentration, (6) cost of mining and milling per ton of ore, and (7) cost per ton of crude concentrate produced. Having given any two or more of these factors, the remaining factors may be determined by inspection from the graph. In constructing the curve it was assumed that 70% of the

zinc and 40% of the iron, as shown by assay, would be recovered, and that the resulting concentrate would contain 10% of gangue.

As an example, assume a certain block of ore has been sampled by churn-drilling or other means and that the average assay shows 6% metallic zinc and 5% metallic iron. Without the curve shown in Fig. 1, the results may be arrived at as follows:

$$70\% \times 6 = 4.2\% \text{ Recoverable zinc.}$$

$$4.2\% \times 1.5 = 6.30\% \text{ Recoverable blende.}$$

$$40\% \times 5 = 2.0\% \text{ Recoverable iron.}$$

$$2\% \times 2.14 = 4.28\% \text{ Recoverable pyrite.}$$

$$6.30\% + 4.28\% \div (100\% - 10\%) = 11.75\% \text{ Grade of recoverable ore.}$$

$$4.2\% \times 100 \div 11.75 = 35.7 \text{ Grade of zinc concentrate produced.}$$

$$100 \div 11.75 = 8.5 : 1 \text{ Ratio of concentration.}$$

The curve shown in Fig. 1, however, represents these derivations graphically for any combination of zinc and iron within the limits of the graph, thus: At the intersection of the 6% 'Zinc in Ore' and 5% 'Iron in Ore' lines read 11.75%, grade of ore; 35.7% grade of the concentrate. Then trace a line parallel to the 'Grade of Ore' lines and through the point of intersection just de-

FIG. 1

terminated, and at the intersection of this line with the 'Ratio of Concentration' line read 8.5:1, ratio of concentration. See dashed line. The cost per ton of concentrate may also be determined from the graph by finding the intersection between a line drawn from a point on the *A-A* axis, whose value corresponds to the ratio of concentration, and is equi-distant from the diverging lines from this axis, and the line corresponding to the desired 'Cost per ton of Ore'. From this point trace to the right until the *A-A* axis is cut and read, 'Cost per ton of Concentrate'. Using the above example and assuming a mining and milling cost of \$1.50 per ton, read on the graph \$12.75, cost per ton of concentrate. See dashed line. With a little practice the dashed lines as shown on the figure can be traced mentally and the above results determined at a glance. In determining the 'Cost per ton of Concentrate', it will be noted that

there may be assumed ten small spaces on the *A-A* axis between every large division and ten small divisions along the line *B-B*, between each of the diverging lines drawn from the *A-A* axis; so that a line may be drawn equi-distant from any two of these diverging lines by connecting points on the *A-A* axis and the *B-B* line located the same number of small divisions from one of the two diverging lines. Where this line cuts the desired 'Cost per ton of Ore' line, read cost per ton of concentrate directly opposite on the *A-A* axis.

In a great many cases experience has shown that in the actual mining of a block of ore considerable more rock is mined than estimated, and that the grade of the ore is less than that figured. This is due perhaps to the fact that ground is broken above the roof as figured, and that mining is carried on outside the assumed areas owing to the lack of a definite line between what is pay-

FIG. 2

ore and what is not, and the necessity of mining barren ground to expedite the mining of indicated ore. The consideration of the character of the orebody and one's experience is about the only method that can be used to determine the value or amount of this mining of ground outside the assumed ore-bearing areas. In the construction of the curve shown, a line was added whereby if it was assumed that an amount equal to 25% of the ore estimated within an area would be mined, in addition to that estimated, and that this 25% outside breakage would contain no metal, the resulting grade of ore of the whole could be read from the graph. See line marked 'Grade of ore with 25% outside breakage'. Using the above example with 25% outside breakage, the grade of the ore as shown by the curve is 9.4%, instead of 11.75%, with no outside breakage. The grade of the concentrates will of course not change, but the ratio of concentration will be increased. The effect of using an outside-breakage factor is practically the same as using a sampling-error, as far as the grade of recoverable ore is concerned.

Fig. 2 represents a series of curves applicable to an ore similar to that found in the Joplin-Oklahoma zinc district, using the following factors or variables: (1) Value per ton of crude ore; (2) recoverable grade of ore expressed in percentage as metallic zinc, zinc-blende, or as 60%-zinc concentrate; (3) market-price of 60%-zinc concentrate; and (4) percentage of royalty to be paid on the selling price of the zinc concentrate. Having given any two of the above-mentioned factors, the remaining factors may be determined by inspection. For example, assume that a certain mine is required to pay 15% royalty on all the zinc concentrate sold, that the ore runs 7% recoverable 'jack', and that the cost of mining and milling per ton of ore is \$2.67; the graph shows the minimum market-price of the zinc concentrate on which operation can be conducted without loss to be \$45. This figure is arrived at thus: From a point corresponding to \$2.67 on the 'Value per ton Ore' axis trace to the right until the 7%-jack line is intersected; thence at right angles until the 15%-royalty line is cut; thence to the right again until the 'Zinc Base when Royalty is to be deducted' is intersected. This point corresponds to \$45.

The graph also shows the equivalents in terms of zinc-blende, and 60%-zinc concentrate for values of metallic zinc within the limits of the curve. For example, the curve shows that 6% metallic zinc is equivalent to 9% blende, or 10% jack as 60% concentrate, or that 7% jack is equal to 6.3% blende, or 4.2% metallic zinc.

A REPORT ON GRAPHITE, just published by the Canadian Department of Mines, points out that Canada possesses deposits of flake graphite superior in richness and quality of flake to any on the American continent. What is probably the largest and richest deposit of flake graphite known in the world occurs in Ontario and is worked by the Black Diamond Graphite Co. Difficulties of concentrating and refining the graphite, however, have long hampered operators. Recently, these difficulties have

been overcome by the employment of the oil-flotation system of ore concentration, which yields far better results than were obtainable by the old methods, both in the richness in carbon of the concentrate made and in the amount of graphite recovered from the ore treated. Several Canadian mills have now been equipped with the flotation process and are producing refined graphite equal, if not superior to, the best graphite on the market.

Production of Zinc

Figures compiled by C. E. Siebenthal, of the U. S. Geological Survey, from reports submitted by all zinc-smelters that operated during the first six months of 1920, show that the production of zinc from domestic ore in that period was 251,065 short tons, and from foreign ore 7043 tons, a total of 258,108 tons, as compared with 210,241 tons in the last half of 1919 and 255,502 tons in the first half. The stock of zinc held at smelters June 30 was 29,892 tons, having decreased from 36,793 tons at the end of 1919, and 59,651 tons at the middle of that year.

From the foregoing figures, and from the statistics of imports and exports, as recorded by the Bureau of Commerce, it is calculated that the apparent consumption for the period was 175,268 tons, as compared with 164,463 tons in the last half of 1919 and 159,501 tons in the first half. In addition to the zinc produced from ore, 12,474 tons was re-distilled from zinc-ashes, skimmings, and drosses. Much of this zinc was of a grade above prime Western, and the total, added to the primary output, gives 270,582 tons consisting of 41,177 tons of 'high-grade', 17,310 tons of 'intermediate', 37,917 tons of 'select and brass special', and 174,178 tons of 'prime Western'. Electrolytic zinc amounted to 24,035 tons, as compared with 3845 tons in the last half of 1919, and with 23,211 tons in the first half. The total number of retorts at plants at which there were some operations during the first half of 1920 is 157,456, as compared with 157,004 at the end of 1919 and with a maximum total of 224,778 on June 30, 1917. The number of retorts in operation on June 30, 1920, was 95,000 as compared with 107,500 at the end of 1919 and 82,000 on June 30, 1919. English zinc smelting is greatly curtailed by high operating charges, and smelters on the Continent are handicapped by heavy fuel costs. Belgium alone is steadily increasing operations, the output of zinc in the first half of 1920 being apparently about 40,000 tons. At the rate of increase which has been maintained since the beginning of the year, the output at the end of the year should be in excess of 14,000 tons per month, or at the rate of about 170,000 tons per year, approximately 80% of the pre-war capacity.

The price of prime Western zinc at St. Louis at the beginning of the year was 9.05c. per pound, but it rose to 9.37½c. by January 9 and then by a long decline, broken by several slight recoveries, reached 7.35c. on June 18, rising to 7.6c. at the close of the half-year. The average for the period was 8.36c. per pound, as compared with 7c. for the year 1919.

The Flue Type of Cottrell Treater

By A. B. YOUNG

***INTRODUCTION.** The object of this paper is to describe a Cottrell treater that was placed in operation in April 1919 at the Tooele plant of the International Smelting Co., for the purpose of recovering solids in the smoke from the McDougall roasting-furnaces. The treater is simply a flue containing rows of vertical plates, forming the grounded electrode, alternating with rows of small horizontal pipes, forming the negative electrode. Means is provided underneath for taking away the dust that collects. This construction has certain advantages over the more cumbersome types, both the vertical-tube and the vertical-box, particularly in avoiding heavy supporting columns and massive foundations. There are no right-angle turns to interfere with distribution of the smoke; consequently there is greater efficiency, or, in other words, a greater volume of smoke per minute can be effectively treated. Another advantage of the horizontal construction over the vertical is that the principle of the selective precipitation of the various components of the fume as it passes along the electric field may be utilized. Since the treater has been placed in operation, the results have been satisfactory, in many ways, particularly in regard to the volume of gas that may be treated.

CONSTRUCTION. In the original design the flues from the roasters delivered their smoke to a large brick dust-chamber that discharged into another flue connecting with the stack, as shown in Fig. 1. The treater is so situated that the smoke is taken by it directly from the chamber and discharged again into the flue. The complete plant will comprise two units, only one of which has been erected at present.

The treater is essentially a flue 10 ft. high, 12 ft. wide, and 61 ft. long. Suspended inside, vertically, and running lengthwise, are four banks of No. 20 corrugated-iron plates; each bank is 10 ft. long, making an effective length of 40 ft. The spacing from centre to centre of the rows of plates is $9\frac{1}{2}$ in., giving 16 rows of plates per bank. Mid-way between the rows is a row of horizontal $\frac{1}{2}$ -in. pipes, running longitudinally; the vertical spacing between them is 6 in. The plates form the grounded, and the pipes the negative, electrodes. Allowing for the thickness of the plates and the area of the pipe-sections, the treater has an effective cross-section of 113.5 square feet.

Steel hoppers that discharge into a screw-conveyor catch the dust underneath; the conveyor delivers into a small bin built in a shaft beneath the treater. This bin may be emptied into cars that are used to charge the reverberatory furnaces and run upon tracks in a tunnel under the large dust-chamber.

The unit is divided into two electrical sections con-

structed in a straight line and operating in tandem. Each section contains two 10-ft. banks of plates, or an effective length of 20 ft. The pipe electrodes are 26 ft. long and extend through both banks of plates. These pipes are supported by three grids, one on each end and one in the middle between the two banks of plates. The intermediate supporting grid is necessary to keep the sag of the pipes within allowable limits. The grid is built up with $1\frac{1}{4}$ -in. pipes that have been bored to allow the passage of the $\frac{1}{2}$ -in. pipes, and is suspended from a beam carried on post-insulators. A box encloses the insulators and the beam on top of the treater, as shown in Fig. 2. The feed-wire is brought into this box through an insulator-bushing. Each insulator is completely enclosed in a small compartment, which protects it from the stream of gas.

The channel-iron beam that rests upon the insulators passes through ring-gaps in the inside walls of these insulator compartments. The ring-gap consists of a ring, made of a $1\frac{1}{4}$ -in. pipe with the ends welded together and welded to a round opening in the wall, and a short length of 10-in. pipe slipped over the beam, making a 2-in. gap. The opening inside the 10-in. pipe is filled with cement.

Each row of corrugated-iron sheets, forming the plates, is suspended, with the corrugations vertical, from the top by means of two angle-irons back to back, making a slot into which the sheets are inserted and secured with bolts. Much the same arrangement is used at the bottom as a guide only. The sheets are not bolted to the bottom angles, nor are they fastened to one another. They must be carefully inspected before being put in the treater, only those free from warp being used. The top of the treater is made of steel plate; and the side walls and the insulator house are made of $\frac{3}{4}$ -in. transite board mounted on a steel framework.

Knocking devices are provided for shaking the dust from the plates and pipes. For the former, there are four knockers, one in each space between the insulator-boxes. The knocker is composed of a shaft, running transversely across the top of the treater, to which hammers are attached, one for each row of plates. The shaft is partly rotated by a handle attached to it, and the hammers strike the angles that support the plates, first on one side of the shaft and then on the other. The two pipe-knockers are similar in design and are arranged to hit the under side of the middle grid of each electrical section. Small doors in the sides opposite the grids enable a man to enter the treater to make necessary repairs.

The treater is supplied with a sliding damper at the intake by means of which all smoke can be shut off, and with a butterfly damper at the outlet. There is a butterfly damper also in the section of the old louvers, one

*A paper to be read at the Lake Superior meeting of the A. I. M. & M. E. in August 1920.

FIG. 1. PLAN OF FLUE SYSTEM

having vertical and other horizontal axes. At the outlet there is one set with horizontal axes. The purpose of these was to regulate distribution, but so far they have not been used.

Nine hoppers underneath the treater collect the dust. The ends, as well as the sides, of these hoppers come up to the floor-line and each is provided with a vertical baffle, which extends through the treater from the floor-line nearly to the bottom of the hopper to prevent gas from leaking through.

ELECTRICAL EQUIPMENT. The electrical equipment for each section is as follows: one 25-kva., 100,000—87,000—75,000—62,500—50,000 to 220-volt transformers; one 31-in. disc-type mechanical rectifier; one 3-hp., 1800-r.p.m., 200-volt, three-phase, 60-cycle, synchronous motor for driving the rectifier; one 37½-kva., 2200 to 220-volt, single-phase transformer; one 1.25-ohm grid-resistor with current-carrying capacity of 100 amp., divided into seven sections; one 2.75-kva., 60-cycle, 220-volt, 22-volt, 125-amp. motor-generator induction regulator; three 7½-kva.,

2200 to 220-volt single-phase transformers; one switchboard panel with necessary meters, etc. In supplying power, the procedure at this treater follows that of the other Cottrell installations of the Tooele smelter, that is, to step down one phase from the smelter main power-line, so that it can be handled on the switchboard. The current is then put directly on the treater-transformer, using a synchronous motor to operate the rectifier. No motor-generator sets are used. The voltage is regulated by means of a grid-resistor, the final adjustment being made by means of an induction regulator, thereby gaining much closer control of the voltage than can be obtained from use of the grids only.

OPERATION. In the operation of the treater, the pipes and plates are cleaned periodically. During the few minutes required for this work, the dampers at each end of the treater are closed and the gases by-passed. Accumulations of the collected

FIG. 2. SECTION OF COTTRELL TREATER

dust not readily removed by the knockers have not been found to interfere with electrical conditions, nor with the efficiency of the treater, probably because of its acid content and high electrical conductivity. After some time, this dust forms a thin permanent scale upon both plates and pipes. This is almost impossible to remove, and might, in appearance, be compared to boiler-scale.

A number of aspiration tests have been made to determine the recovery obtained by the treater for actual gas-velocities varying from 15 to 22 ft. per second. Typical recoveries, which vary little within this range of velocity, are shown in the following table:

Metal	Recovered %
Copper	98.2
Lead	81.2
Silver	96.5
Gold	96.4
Total recovery	93.97

The velocity through the treater, under actual conditions of temperature and pressure, is 21.45 ft. per second; the volume is 146,004 cu. ft. per minute. The temperature at the outlet averages 260°F., and at the inlet, 280°F. The uniformity of distribution is probably responsible, in large measure, for the efficiency attained with the high velocity, which is approximately equivalent to a breeze at 15 miles per hour. The upper limit of velocity for 40 ft. of plate-electrode has not been determined, but a material drop in recovery has been noted at 31 ft. per second.

It has been mentioned that advantage may be taken of the principle of selective precipitation in this type of Cottrell treater where the composition of the dust or fume is such that the recovery of several products is pos-

sible. Table I shows the distribution of the various components of the dust drawn from the successive hoppers underneath. The hoppers are numbered beginning at the intake.

Table I—Analysis of Dust

Hopper No.	Copper %	Lead %	Silver, ounces per ton	Gold, ounces per ton	Insoluble, %	Iron, %	Sulphur, %	Lime, %
1	8.30	3.2	6.84	0.45	19.7	18.7	14.3	2.6
2	8.30	3.7	6.26	0.44	20.6	17.1	14.0	2.6
3	7.60	5.3	6.82	0.38	20.0	17.3	14.0	2.5
4	7.00	6.8	6.96	0.34	19.2	15.3	14.7	2.3
5	6.00	8.2	5.94	0.30	16.8	13.4	14.7	2.1
6	5.15	11.6	5.90	0.27	16.1	12.3	14.0	2.2
7	4.55	13.1	5.36	0.24	13.5	10.2	15.5	1.7
8	3.95	15.5	4.80	0.19	11.4	8.7	15.2	1.5
9	3.80	14.8	4.30	0.19	10.3	8.4	16.2	1.7

The outstanding feature is the constantly decreasing copper content and increasing lead content as the outlet is approached, thereby permitting a portion of dust to be segregated and smelted for its lead. An examination of the figures for iron and insoluble bears out the idea that there is a marked tendency to precipitate the true dust particles near the entrance, and that the more impalpable fume must travel farther through the electric field before being caught.

It is extremely difficult to state accurately the power-input to the treater, other than that it is lower than usual and varies considerably. For normal gas-volumes (125,000 to 150,000 cu. ft. per minute), the input of power will average close to 8.4 kva. for the first electrical section and 5.5 kva. for the second. Approximately 85% of the dust caught is collected by the first and 15% by the second section. Sphere-gap peak-voltages run from 30,000 to 35,000, and occasionally higher; they are usually about 1000 to 1500 volts higher in the second than in the first section.

FIG. 3. ANOTHER SECTION OF THE TREATER

In conclusion, it may be said that this form of treater has proved admirably adapted to this particular smoke. Its ability to treat a purely fume product satisfactorily is an unsolved question, no data being available for its performance in this regard. However, when one compares the compact flue-like building, which is efficiently handling 150,000 cu. ft. of gas per minute, with the complex towering structures of the vertical type necessary to treat a like amount, a distinct forward step is apparent.

Credit should be given to O. M. Kuchs, assistant general manager of the International Smelting Co., for the suggestion of the horizontal electrode and the use of pipe for this purpose, thereby making the adaptation of the plate-type treater to a horizontal flue feasible; to R. B. Sumner, mechanical superintendent of the Tooele smelter for its design; and to B. L. Sackett, superintendent of the lead-plant at the Tooele smelter for the experimental work done in its development.

The Paddy Pride Mine

The Paddy Pride Silver Mining Co. owns the Oversight group of five claims, nine miles west of Zabriskie, California, a station on the Tonopah & Tidewater railroad. The claims are in a rugged country consisting of a series of irregular, rough, and jagged limestone hills at the southern end of the Funeral range. The claims are at an altitude of 1500 ft. above Zabriskie. Water is hauled from Shoshone, 16 miles distant, over a good wagon-road, the last mile of which is steep and winding.

The outcrop was found at the top of the ridge and some rich lead-silver ore was shipped from it. The outcrop was then traced along the side of the hill and a 150-ft. tunnel was driven in the vein, cutting it at a depth of 180 ft. At 150 ft. from the portal there is a fold in the vein and a raise was driven, the continuation of the ore being found. Raises and two winzes were sunk in ore. There is a 50-ft. inclined winze 50 ft. from the portal of the tunnel and a 25-ft. vertical winze 110 ft. from the portal. The ore is persistent in these winzes and in a drift from the vertical one there is rich ore.

One carload of ore that netted \$1400 and another that netted \$1270 were shipped from these workings, but because of the expense of mining through the winzes it was decided to drive another tunnel, lower in the vein, that also would be more accessible for the wagons in which the ore was hauled to the railroad. This tunnel, being driven toward the hanging wall, has not yet reached the vein.

The ore is lead-silver. The lead is mostly in carbonate form, with some galena, the amount of sulphide not increasing rapidly with depth. There is carbonate of lead at the bottom of the 110-ft. winze, showing that the zone of oxidation extends much deeper. The rich ore is in seams parallel to the bedding planes of the shale and the seams continue into the limestone as far as the fracturing exists. The average width of the fracturing is 8 ft. The silver content of the ore varies from $\frac{1}{2}$ oz. to each per

cent of lead in the richer ore to from $\frac{3}{8}$ to $\frac{1}{4}$ oz. to each per cent of lead in the lower grades. Shipments show the gold value to be as high as \$4 per ton, with 4% iron, 20% lime, and little magnesia. A 25-ton shipment to the American Smelting & Refining Co. had the following content:

Gold, 102 oz.; silver, 24.4 oz.; lead, 45.9%; copper,

PORTAL OF PADDY PRIDE TUNNEL

1.25%; zinc, 6%; sulphur, 8%; iron, 3.3%; insoluble, 11.8%. The smelting company paid \$56.43 per ton for this shipment.

The ore is valuable to the smelters because it contains a large proportion of lime and some iron, so that a reasonable contract can be made for treatment and low-grade ore can be handled at a profit.

A METHOD of blasting a heading, possessing a new feature, is reported from the Nordhausen mining district in Germany. Instead of two or three inclined shot-holes in the centre to un-key the face of the work, the holes are bored parallel with the axis of the drift, locally known as 'canon-shots'. These are arranged and fired to make a hole of no great diameter in the centre of the face by crushing the rock. Then a ring of shot-holes is bored around this central opening and fired. This removes a considerable mass of rock, thereby greatly enlarging the central opening. Another ring of holes, more widely spaced, clears the face. The novelty consists in the closely situated central crushing holes. Being so near together, it is not necessary to have a primer and fuse in each. The concussion of one shot is sufficient to fire the rest.

New Hoisting-Equipment at the Tonopah Extension Mine

*The Tonopah Extension Mining Co. has recently completed a number of improvements in its surface-plant, for increasing the capacity of its Victor shaft and permitting deeper mining under advantageous conditions. These improvements include a change-room to accommodate 156 miners, new bins for ore and waste, a 100-ft. steel head-frame, and a new building to house compressors of increased capacity, and a new electrically-driven hoist. A number of features in the design and construction of the hoisting equipment are of special interest.

The hoisting-engine was built by the Nordberg Manufacturing Co., of Milwaukee, and is of the double-drum type, each drum running loose on the shaft, with a hydraulically operated clutch and brake. The hoist is connected through a single reduction of herringbone gears to a 300-hp., three-phase, 440-volt, 60-cycle motor, running at 600 r.p.m. It was manufactured by the General Electric Co. The current is fed to the motor through a magnetically controlled switchboard. A Francke all-metal flexible coupling is interposed between the pinion and the motor.

The hoist was designed to handle, for continuous duty, when in counter-balance, a total load of 8 tons, which includes the weight of the rope, from a maximum depth of 3000 ft. Each part, however, is of sufficient strength to permit hoisting an unbalanced load when necessary. The drum-shells, which are cast in halves, are constructed of hard close-grained cast-iron. They are machine-grooved over the entire face for $1\frac{1}{2}$ -in. rope, having a pitch-diameter of 72 in. with a winding-face of 66 in. The drum makes 54.8 r.p.m., giving a rope-speed slightly in excess of 1000 ft. per minute.

Hydraulic operation of brakes and clutches, together with automatic safety-devices, are important features and are marked improvements over many types of hoist that have preceded this design. The brakes and clutches are operated from the engineer's platform in much the same manner as with the direct-brake type of hoist. The brakes are applied by means of dead weights and are released by a direct-acting thrust-cylinder, the motive power for which is oil, from an accumulator, which is maintained at a pressure of approximately 105 lb. per square inch. The clutch-cylinders are of the differential

double-acting type, applying the clutch on the forward stroke and releasing on the return. Oil is admitted to, and exhausted from, the thrust-cylinders by hydraulic valves so constructed that it is impossible for the inlet and exhaust-valves to be open at the same time; the arrangement of the mechanism is such that the movement of the hydraulic valves, and therefore the thrust-cylinders, follows absolutely the motion of the operator's lever. Whenever this lever comes to rest, the thrust-cylinders also come to rest and are securely locked in that position, due to the fact that both hydraulic valves

HOIST-ROOM AT THE VICTOR SHAFT. TONOPAH EXTENSION MINING CO.

are closed. Accordingly the operator has full control over the brake mechanism, in the same manner as he would with direct action of the brakes, but the operation is accomplished with less effort; it is more positive and permits of a smoother handling of the hoist.

The accumulator is a cylinder 40 in. diam. by 48 in. long, outside dimensions, provided with a vertical fixed plunger that permits the oil-filled cylinder to rise or lower. The oil-supply is maintained in the accumulator by two $1\frac{1}{2}$ by $2\frac{1}{2}$ -in. direct-connected vertical triplex pumps. One of these pumps has sufficient capacity to operate the accumulator, the other being a spare. When oil is fed to the thrust-cylinders, the displaced oil causes a slight movement downward of the accumulator, as the oil drawn from the feed is in excess of that supplied by the pump during the same period of time. However, the

*Data furnished through the courtesy of John G. Kirchen.

capacity of the pump, working continuously, is in excess of the total amount of oil required for the periodic feeds to the thrust-cylinders so that the accumulator is usually held at, or near, the upward limit of travel, at which point a by-pass opens and allows the excess oil to return to a well from which the pump draws its supply, and to which all of the oil exhausted from the thrust-cylinders is returned. The accumulator has a travel of 36 in. on its fixed plunger, thus having ample reserve during periods when the feed to the thrust-cylinders may exceed the capacity of the pump, such as might occur during a series of closely intermittent starts and stops, or more especially when the clutches may be repeatedly shifted. The quantity of oil required to fill the entire circuit is approximately 50 gal. A light grade of dynamo-oil is used. The use of heavy oil should be avoided, especially under conditions of temperature that would tend to lessen its fluidity.

The safety-devices consist of a solenoid-operated valve that functions in connection with the brake-operating levers. A Welch controller works in connection with the solenoid, which will open the solenoid-circuit and automatically shut off the power from the hoist-motor under any of the following circumstances:

1. If the hoisting-speed exceeds normal at any point.
2. If the operator fails to slow-down the hoist at any predetermined and adjustable point, and further fails to continue to slow-down between this point and the landing-level.
3. In case of overwind.
4. If the operator fails to reverse the hoist after the skip or cage has reached the landing, or limit of travel.
5. If the power goes off for any cause.

Should any of the above conditions arise, the solenoid is immediately de-energized. The solenoid circuit is then thrown open, the hydraulic brake-valves opening simultaneously, and allowing the oil to be exhausted from the hydraulic-brake cylinders; and the brakes are applied by the dead weights, the entire operation occurring automatically, smoothly, and almost instantly. The solenoid, with its counterweights, is placed at the front of the engineer's platform, while the controller, together with the rest of the safety mechanism, is supported on the indicator-column and is driven from the drum-shaft by the same sets of gears and shafting that operates the indicators.

Lead and Zinc in Japan

Lead is mostly found in the form of galena, which is closely associated with zinc-blende ores. The principal lead mine in Japan is the Kamioka, in Gifu Prefecture. The Mitsui Mining Co. in 1918 produced at this mine 7,408,309 lb. of lead, says a recent Commerce Report.

Producers and smelters were buoyed up by the high prices ruling during the War and by the hope that strikes and political conditions in the United States, Spain, Australia, and Mexico, the principal lead-producing countries of the world, would create a world-wide shortage.

However, this hope does not seem to have fully materialized, and the lead market has become quiet as a consequence. The increased cost of materials for smelting and higher wages has caused a considerable reduction in output as compared with 1917. If the 1919 figures were available they would undoubtedly show a still more noticeable decrease in amount and value, many of the companies having experienced financial difficulties. In 1915 Australia sold to Japan 24,599,868 lb. of lead ingots and slabs, valued at \$1,102,933. The same year the United States sold to Japan 5,790,156 lb., valued at \$248,307. In 1919, while imports of lead slabs and ingots from Australia had only increased to 32,366,341 lb., imports from the United States jumped to 27,239,280 lb. In 1914 Japanese consumption of lead was estimated at 43,753,000 lb., a great share of which was imported from Australia. In 1918 the estimated consumption had reached 144,025,000 pounds.

Only since 1913 has Japan engaged in smelting zinc. Prior to that time zinc ore was shipped abroad and the refined product then imported. The largest zinc mine is Hikoshima in Yamaguchi Prefecture. In 1918 the production of this mine was given as 27,672,960 lb. of zinc and 230,720 lb. of lead. The estimated consumption of zinc in Japan increased from 25,512,000 lb. in 1914 to 60,761,000 lb. in 1918. The estimated cost of production of refined zinc, at the smelters, is about \$11 per picul (133½ lb.). Prices of 98% zinc ranged from \$6.41 in June 1914 to \$27.40 per picul in December 1915. Since then prices have hovered around \$12 as an average. In March 1920 the price was \$13.96 per picul. The margin of profit, considering transportation charges, is thus proportionately low at present. Yamaguchi Prefecture led in zinc production in 1918 with 27,672,972 lb., valued at \$2,535,822. Fukuoka and Okayama followed in the order named, with over 18,000,000 lb. each.

In Japan, the principal uses of lead are for the making of paint, cables, and piping, and in producing acetic acid. The principal uses of zinc are for plating and making paints. In the mining of lead and zinc, primitive hand methods are used by the smaller companies. The operations of the larger ones, however, compare favorably with those used in the Coeur d'Alene, Idaho. There are 2364 miners employed in zinc mining, while 1046 are employed in lead mining. The Mitsubishi Kogyo Kaishiki Kaisha pay their miners an average of about 75c. per day, with two holidays per month. The underground miners work about 56 hours per week; surface workers usually have a 77-hour week. During 1917 and 1918 a great deal of zinc ore was imported for smelting, mostly from Australia. However, since 1918 imports of zinc ore have decreased considerably, owing to a smaller foreign demand for the refined article, thus causing many smaller smelters in Japan to suspend operations.

The exports of zinc ore have shown a steady decline since 1915, when they amounted to 13,618,250 lb. On the other hand, exports of zinc ingots and slabs increased until 1917, since when they have shown a noticeable decrease.

Flotation Processes

*The announcement that the Minerals Separation Company is ready to do business in the United States marks an interesting epoch in the history of the flotation processes. It is signalized by the formation of a company incorporated under American laws, with Mr. E. H. Nutter as manager. This method of concentration has hitherto received but little attention in America, chiefly because no one skilled in such operations has been on the spot to demonstrate the application of the principle involved. This disadvantage has now been removed, and metallurgists on the other side of the Atlantic will have an opportunity of judging for themselves. Concurrently with the establishment of an American branch of the Minerals Separation Company, the 'Engineering and Mining Journal' publishes an editorial in its issue of April 25, attacking the validity of flotation patents in general, and those of the Minerals Separation Company in particular. The 'Journal', after maintaining for five years an attitude of incredulity as to the practical value of a new-fangled notion, now shifts its ground, and argues that the same thing was done twenty years ago in the United States. Thereupon it recommends American metallurgists to go ahead for themselves, and not be frightened with threats of litigation on the part of the proprietors of the process now introduced to their notice. We abstain from making more than passing reference to the personal considerations that may explain this unfriendly attitude toward Minerals Separation, merely ejaculating, with Mr. Vincent Crummies, of immortal memory: "How *do* these things get into the papers!" How indeed! It is not for us to say. But seriously, and on general principles, we wish to warn American metallurgists that the history on which the article in the 'Journal' is based is incomplete and the application inaccurate. In our issue of September 1909 we published a detailed account of the various patents from 1860 onward, covering the selective action of oil, and the flotation by gaseous bubbles, oil, and surface-tension, and we recommend American metallurgists to read this article for themselves. A careful perusal of it will show that the subject is much more complicated than the editor of the 'Engineering and Mining Journal' would have it supposed. Of course, all these old attempts to utilize oil, acid, bubbles, etc., were perfectly well known to Elmore, Cattermole, and others who have applied themselves to this branch of metallurgy. For instance, Elmore only claimed the application of the principle to a freely flowing pulp, that is, he considered his invention to consist in the continuity of the process and in the use of large volumes of water. This claim was, however, not upheld in the English courts, although the German Patent Office recognized its novelty; while in Australia the decision of the law on the subject has not yet been reached. The Minerals Separation Company, which owns the series of patents of Cattermole, Sulman, Picard, and

Ballot, bases its main claim on the use of minute quantities of thin oil for the purpose of creating the froth that collects and buoys the sulphide particles. Both of the belligerent groups have patents for modern applications of an old idea, and their patents will cause trouble to those who wish to work the processes on their own account. So we recommend American metallurgists not to be in a hurry to follow the 'Journal's' advice.

An editor may have some difficulty in deciding which line to follow: whether to fight for the perfect freedom of every process and so benefit metallurgists and operators generally, or to appeal for fair play to the individual metallurgist, who by years of thought and hard work has evolved a commercial process out of a chemical or physical idea. His decision is usually made according to the degree of reasonableness on the part of the inventor. If the inventor is too grasping, general resentment is aroused; but if he is reasonable in his demands, he ought to be allowed a legitimate reward. In the case of flotation processes, the owners are not avaricious; their terms of royalty and co-partnership are quite businesslike. There remains a further reason for recommending metallurgists not to embark rashly on the sea of investigation and invention for themselves, namely, the complexity and obscurity of the physical forces that underlie the phenomena of flotation. By all means let them make examinations of the problem, for we want more light on it—and less heat—both from scientific and practical men. But our advice is that they should not do it at the expense of a mine, for it will come cheaper to engage the services of an expert, who has had a few years of experience, and to pay him a reasonable royalty, than to spend time and money on research work in the hope of evolving a commercial plant that will dodge the payment of a small royalty.

There is another feature of the 'Engineering and Mining Journal's' advice that is open to objection. The question of the validity of patents is entirely one for the courts to decide, and it is useless for an editor to pass an opinion as to the legal standing of the various patents. If an editor has information that will help in the elucidation of an intricate dispute he is fully justified in publishing it, and in giving his interpretation of it, but to present an incomplete statement that practically evades the main question is only a trespass on the legal domain. In this connection it has to be remembered that several lawsuits are about to be tried in Australia and for this reason alone one-sided statements and comments by influential papers, though published on the other side of the Atlantic, are to be deprecated. The Elmore v. Minerals Separation case will be commenced on May 22. The Potter Company, which has the rights to hot acid solutions, is also bringing action against Minerals Separation. As for the De Bavay Co., nearly all the other patentees claim that its process, though not necessarily its patents, is an infringement of their rights, therefore we suppose that it would be to the interest of this company that every patent should be upset in Australia, America, and elsewhere.

*An editorial from 'The Mining Magazine' of May 1911, introduced as evidence before the Federal Trade Commission.

The Mines at Chuquicamata

*Chuquicamata, lying at an altitude of about 9200 ft. above sea-level, is at the end of a spur of the Antofagasta & Bolivia railway, about 14 miles distant from Calama, with which it has daily train connections. The latter town is 150 miles north-east of Antofagasta. The mines situated at Chuquicamata are the property of the Chile Exploration Co., a subsidiary of the American Smelting & Refining Co., and the present plant began production in May 1915. It is said that the works at both Chuquicamata and Tocopilla represent a total investment of about \$100,000,000.

The mining operations are simple. The ore, ranging from 1.5 to 2% copper, is shoveled directly from the side of the mountain into the cars, which carry it down to the crushers. There are three different series of these. The contents of the cars, holding 90 tons, are dumped into the primary jaw-crusher, which breaks up the large pieces of the ore. Thence the ore is carried by belt-conveyors into storage-bins, from which it is drawn off underneath by belt-conveyors and sent to the gyratory crushers. These still further reduce the ore, after which it is passed to Symons disc-crushers. It leaves the latter in condition to be treated in the leaching-plant. Belt-conveyors, more than 1000 ft. long, carry the ground ore to the large leaching-vats, where it is treated with water. There is sufficient sulphur in the ore to form copper sulphate, without the introduction of sulphuric acid, although before this fact was discovered the company had installed an elaborate acid-plant, since abandoned. After four days the liquid copper-sulphate solution is drawn off and carried to the large tank-house, where the copper is deposited electrolytically in sheets, about 2 by 3 ft. in size. These sheets of pure copper are then hauled to the smelter, where they are cast into bars 5 ft. long and 5 in. thick, ready to be shipped.

The monthly production of copper is now between 3000 and 4000 tons, and an increase in the capacity of the plant is being planned. The cost of production per pound, including transportation to New York and selling costs, is about \$0.145.

The company has two railway lines of its own on its property, one of standard gauge and another of the same gauge as the Antofagasta & Bolivia railway—in all, about 50 km. of track. Moreover, it owns 50 locomotives of three different types. Since the terminal of the spur from Calama is at Punta de Rieles, a short distance below the town of Chuquicamata, the company has constructed a track from this point into its own plant, thus making it possible to load the copper bars directly onto the cars at the smelter, and to unload all the materials brought in from the outside for the use of the plant. The entire product of the mines is shipped from Antofagasta, in part by the company's own boats and in part by independent steamers. However, the company is now seriously considering the building of a line almost due west to the coast at Tocopilla, which lies much nearer to the

mines than does Antofagasta, and, moreover, is situated farther up the coast and therefore nearer New York.

Power for the plant at Chuquicamata is supplied by electricity brought from the company's power-station at Tocopilla; 100,000-volt current is distributed through a large transformer station. Between 50,000 and 80,000 bbl. of fuel-oil is used at Tocopilla each month, and from 25,000 to 30,000 bbl. at the plant itself, largely for the smelter and the locomotives. The water for the use of Chuquicamata is brought a distance of 90 km. from near the base of the volcano of San Pedro. It is said that the building of this system alone cost \$1,000,000.

Chuquicamata, or 'Chuqui', as it is generally known, is one of the largest mining camps in the world; the total population is about 10,000. The mine is situated two miles from the town and nearly 1000 ft. higher. The town itself is divided into three parts. On one side is the 'American town', consisting of the houses occupied by the American employees, the hospitals, the clubs, and the offices of the company. The American and English employees number between 200 and 250 and are employed on a three-year contract. Next to their settlement is the plant proper—the crushers, leaching-vats, shops, tank-house, electric station, smelter, etc., and beyond lies the so-called 'new camp', or town, where the workmen live. These laborers, consisting of both Chileans and Bolivians, are housed in neat and comfortable plaster buildings of which there are altogether some 1300. Wages range from 7 to 25 Chilean pesos per day (about \$1.40 to \$5). Homes for the American and better-paid Chilean employees are noticeably well built, equipped with heating apparatus and modern plumbing, and are furnished as attractively as possible. The total number of residence buildings at Chuquicamata is 1795. Visitors to the plant may stay at the 'Guest house', where excellent accommodations are supplied for 18 pesos per day.

A welfare manager has charge of the housing of all employees, as well as of sanitary conditions, amusements, and the general welfare of the native population of the town. There are public baths, and a sewage system covering the whole camp, and the sanitary regulations made by the welfare department are rigorously enforced. Two hospitals with attendant doctors and dentists are maintained by the company.

Education is furnished by two schools, one for American children, who are taught by American teachers, and another for the children of the Chilean workmen. Several hundred pupils attend the native school, which is housed in an attractive concrete building and equipped as well as any American school of equal grade. A church has also been constructed, and is in charge of a resident priest. Two club-houses are furnished for the American employees, one of which is said to be among the finest in Chile, possessing with other features a swimming-pool, dance-hall, bowling-alleys, and billiard-rooms. Other club-houses are available for the native laborers. A large theatre displays moving pictures for the benefit of the whole population of the camp. In addition, there are golf-links, tennis-courts, football-fields, and a race-track. The camp does not lack amusement.

*W. L. Schurz in 'Commerce Reports'.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

CONDITIONS AT THE U. V. X. MINE.

JEROME.—The reverberatory furnace at the United Verde Extension smelter was blown-in last week and is operating satisfactorily. The roasting-plant is also in operation, and as a result of this expansion the Extension is adding to its smelter force. From a recent report issued to stockholders by the United Verde Extension on underground conditions it is learned that the ore-bearing area on the 1500-ft. level is approximately two-thirds the size of that on the 1400, and the copper content is about 6%. Development work on the 1600-ft. level has reached the orebody and it is understood that the first samples were in the neighborhood of 5%. Similar work on the 1700-ft. level will not cut the orebody for some time to come.

The tunnel at the Shea Copper Co. is now at a point immediately below the shaft and a station is being cut for the raise, which will be begun to connect the tunnel-level with the shaft 200 ft. above. In the meantime the tunnel will be advanced to cut the orebody developed on the 325-ft. level west of the shaft. The orebody is now dipping to the west and it may require as much as three weeks to advance the tunnel to the intersection. The width of the vein was determined when cutting the station and an interesting point is that the walls have changed from diorite to porphyry, the latter being associated with the orebodies opened on the upper levels of the mine. While the tunnel was being driven, a small crew has been at work on the stope west of the shaft on the 325-ft. level and several cars have been shipped to the Extension smelter. The ore coming from this stope is of as high a grade as any yet found in the mine and expectations are that with the additional depth afforded by the tunnel steady shipments can be maintained as soon as the new bore cuts the orebody.

AJO.—The New Cornelia Copper Co. has declared its second dividend of 25c. this year—the third since the initial payment, made the latter part of 1918. The New

Cornelia is rapidly forging to the front as one of the leading copper producers. Ore shipments were commenced exactly three years ago. The New Cornelia is controlled by the Calumet & Arizona, through ownership of 1,229,741 shares of its 1,800,000 shares of outstanding stock. Dividend payments by New Cornelia therefore benefit Calumet & Arizona to a considerable extent. The recent 25c. dividend, payable August 23, will call for the distribution of \$450,000. New Cornelia last year produced 39,509,000 lb. of copper, and sold 29,972,106 lb. The copper on hand at the close of the year was inventoried at 12½c. per pound. While the company last year

LEACHING-PLANT AT THE COPPER QUEEN MINE, BISBEE

showed a net income of but \$17,246, this was after charging off \$641,861 to depreciation and \$897,144 to ore depletion. The sum total of these two charges alone was equivalent to about 85c. per share on the stock.

OATMAN.—It is reported that the owners of the Gold Dust mine at Oatman are preparing to install a milling-plant. The company has machinery that can readily be converted into a plant capable of handling the product of the mines with small expenditure of money.

COCONINO COUNTY.—It is reported that plans are under consideration for the construction of a railroad that will run from Flagstaff to Winslow and thence through the northern part of Arizona to New Mexico, Utah, and Colorado points, in order to tap the rich coalfields and mineral deposits of Arizona and New Mexico, and also connect with eastern lines.

COLORADO

CAPACITY OF SMUGGLER UNION MILL BEING INCREASED.

LEADVILLE.—Mine buildings and equipment at the Ponsardin mine that were recently destroyed by fire, believed of incendiary origin, are to be replaced by the lessee, W. E. Bowden, and as soon as the new plant is in operation shipments of tin and lead will be resumed. The force at the Northern will be doubled immediately, according to S. M. Carleton, manager, and two shifts operated. The Rio Grande Railway Co. will re-lay track to the mine and ore is being stored underground rather than incur the high cost for haulage by team. A strong body of manganese ore was recently opened at the Newell shaft and is now under development. Operation of the District mill has been unsatisfactory and it is doubtful if the plant is kept in operation. The test run has shown the mill to be "expensive, inconvenient, and unsatisfactory", according to the manager's statement. Development is in progress by the C. & H. Mining Co. in the Graham Park section, operating through the Star of the West shaft in search of the Iron-Silver shoot believed to extend into this property.

TELLURIDE.—Shipments during July from the Tomboy mill totaled 60 cars of concentrate; the Smuggler Union billed out 35 cars. The last-named plant is turning out about 400 tons of concentrate daily. Work is progressing on the new flotation unit and when completed the Smuggler mill will handle 700 tons per day. Lessees at the Favorite mine at Ophir are shipping smelting-grade ore.

BRECKENRIDGE.—Fire of unknown origin destroyed the sawmill of the Royal Tiger company last week, together with timbers for mine and the new concentrating plant, now in course of construction. The delay to operations will be expensive. A flotation unit has been added to the plant of the Liberty Mining & Reduction Co. on the Pennsylvania group. Lessees who have been operating on the property shipped two cars to the A. V. smelter at Leadville last week. The electric-power line to the Deep Shaft mine of the Tymos company on Shock hill has been connected, and a second shift is cross-cutting to connect with the Brooks-Snyder workings for ventilation. With ventilation provided the Deep shaft will re-enter the shipping list after a long period of inactivity.

CENTRAL CITY.—A rich body of lead-silver ore has been opened at a depth of 35 ft. in the Alaska mine, above Black Hawk in Gilpin county, by the Midwest Mining Co. Rich lead ore containing native silver is being sacked, while the concentrating ore is treated at the Iron City plant with good profit to all interested. The Comstock, operated by a syndicate of Ohio capitalists, continues shipments of concentrate and smelting ore. The main shaft is to be sunk to greater depth and the property long inactive is to be thoroughly exploited.

Rich gold ore has been opened by former Cripple Creek men, on the Gold Rock in Russell gulch. The lessees, who have an option to purchase, are McLean and McCampbell. Ore uncovered at the 450-ft. level has given assay returns of 48.60 oz. gold, 100 oz. silver, and 15% copper,

a total of \$1100 per ton. The property was operated 13 years ago by the same McCampbell, who cut but passed up the narrow streak that is now yielding this rich ore. McCampbell carried up a short raise where the streak widened to 12 in. The stope is now 18 ft. in length with ore in both ends and overhead. The Rara Avis in Eureka gulch has been taken under bond and lease by Steve Hoskin, of Denver, and Kansas City associates. Electric equipment is being installed.

CRIPPLE CREEK.—The crew testing the formation in the north-east end of the district has drilled more than 1150 ft. and for 150 ft. change in the character of the rock has been noticed. Small seams of quartz, showing mineralization in pyrite with slight flourine stain, have shown in the core of the drill, and conditions are considered most encouraging. Progress is being made at the rate of about 20 ft. daily. Samples of the drill-core have been sent to Denver for assay.

MICHIGAN

RESUMPTION AT FRANKLIN ANTICIPATED.

CALUMET.—Calumet & Hecla, by August 18 or 20, will have caught up on unfilled orders for France. A recent order for that country, 1500 tons, called entirely for special shapes, including bars weighing 265 lb. to be used for wire-drawing, and billets of from 150 to 400 lb. each for seamless tubes. A small quantity of cake-copper, ordinarily used for sheets, also was included in the order. In the meantime, comparatively small orders for domestic consumers are being filled, the last of which was 350 tons. Shipments are about on a par with production and the curtailed operations actually leave a smaller surplus on hand than was reported a year ago.

Planned improvements at the Calumet smelters have not gotten beyond the blue-print stage and as long as prices of material continue so high, it is not expected that work will begin. Construction work at the Calumet mills is confined to the erection of the addition to the flotation plant. With the extra equipment installed and in operation, a further recovery from the conglomerate tailing will be possible, as all the slime then will be treated by the oil-process. Only two-thirds of the slime-tailing is at present treated by flotation, yet the reclamation-plant is yielding 1,400,000 lb. of refined copper per month.

Allouez reports 11,120 tons of ore for July against 18,750 tons in June, and its shipments, representing the cleaning-up process in the stopes since its recent suspension, at present are not more than 250 tons per day, while Centennial's shipments have ceased completely. Superior in July shipped 1275 tons to the Osceola mill and LaSalle's, July production was only 375 tons. Isle Royale has been making no overflow shipments for three or four months and its production is held at about 50,000 tons per month, all of which is stamped in its own milling-plant. Arcadian Consolidated is making splendid progress in the sinking of its New Baltic shaft from the 500 to the 900-ft. level, with two machines operating two shifts per day. The next project, once the sinking is completed, will be the driving of a drift south to connect

with New Arcadian's north drift on the 900-ft. level. When completed, the drift will be 3400 ft. long. On the 500-ft. level a cross-cut was driven 15 ft. to the vein, which revealed a width of 18 ft. and encouraging copper content. The showing, in fact, was as good as on the 400-ft. level where rock that will yield at least 25 lb., it is estimated, was opened.

Seneca reports a fair showing in Gratiot, while the miners freely assert that the developments during the past week are by far the best since the south drift on the 13th level started. The improvement in the level has been persistent and there is every reason to hope for a continuation of present or even higher grade as the drift approaches Mohawk No. 1 shaft boundary. In Seneca proper, preparations are being made to sink below the fifth level. Concreting keeps abreast with sinking and no delays will be experienced when capacity production begins. The drifts on the fourth level, north and south, are in excellent ground and on the third level, north, there is a marked improvement in quality.

Franklin shareholders on the lake are eagerly awaiting a resumption of operations at the property. From all indications the prospects of the mine were never better than they are at present. Operations on the 39th level seemed to inject renewed life into friends of Franklin, for good prospects are known to exist 700 ft. north, and perhaps up to the 30th level. There has been no mill-test of the rock in the lower workings, but the mineralization was persistent from the shaft to a point 700 ft. distant, and the rock should assay 25 lb., refined, per ton. The operations in No. 1 shaft have been confined to the one lode, the Pewabic amygdaloid, while in No. 2 shaft the Allouez conglomerate is promising and may prove to be profitable.

NEVADA

CONTROL OF SIMON SILVER-LEAD PROPERTY MAY BE ACQUIRED BY INTERNATIONAL NICKEL CO.

DIVIDE.—There is little doubt in the minds of many who have followed the Tonopah Divide developments closely that in a few months a report will be issued that will place the ore-reserves at a figure approximating that given by A. I. D'Arcy before he resigned as consulting engineer. It is said that in two or three months the mine is to be re-sampled in preparation for the issuance of this report and that until then the main effort will be to block out ore on all levels, particularly on the third, fourth, and fifth, where the south-east drifts are said to have been turned from the vein by the former management.

MINA.—Ore has been found on the hanging-wall side

of the vein on the 550-ft., or bottom, level of the Simon Silver-Lead. A raise was driven on this level and at a height of 50 ft. the orebody was entered. The raise has been in ore for 15 ft. and a cross-cut on the level is expected to cut this ore within 40 ft. P. A. Simon, president, has denied the rumor that the International Nickel controls the company. He said, however, that the sale of a controlling interest to the International had been discussed and may be discussed again.

GOODSPRINGS.—T. J. Renaux has been appointed to succeed M. P. Cloonan as mill-superintendent for the Yellow Pine company. E. F. Gordon, of the Vanadium Corporation of America, and Oscar Hershey, of Burch, Hershey & White, consulting engineers of San Francisco, are here to inspect the vanadium-producing mines, the owners of which are seeking to find the best method of marketing their product. The Yellow Pine shipped

PORTAL OF THE STERLAG TUNNEL AT STONEWALL, NEVADA

during June, 21 carloads of zinc concentrate, 5 of lead concentrate, and 9 of zinc slime. Nine cars of ore were shipped from other mines.

GOLDFIELD.—The Development company has levied assessment No. 2, for 2c. per share, delinquent September 4. A. I. D'Arcy, vice-president and general manager, in a statement to stockholders, says that since June 16, when it was started, to July 30, there was delivered to the mill 4800 tons of ore of a gross value of \$45,690, or \$9.50 per ton. The last 800 tons treated before July 30 had a gross value of \$16.20 per ton, according to the statement. Indications are that the extraction will be 90% and Mr. D'Arcy says, "as a matter of fact the tailing has shown an assay value of but 40c. per ton." He estimates the net profit from July 16 to July 30 at \$12,000. The first large clean-up will not be made until September 15 and Mr. D'Arcy says "notwithstanding that our operations are showing a profit, it will be necessary to provide additional funds with which to meet payrolls, cost of supplies, settlement for custom ore treated, and other expenses falling due before we can realize on our bullion and con-

concentrate shipments." He gives this as the reason for levying the assessment and by September 15 "returns should well exceed expenses and the operation show a tangible profit", according to the report. The mill is now treating 100 tons of ore daily, an average of 30 stamps being used. All of the crushing is done on one shift.

WEST DIVIDE.—Zeb Kendall has bought the interest of Al McCoy and George Cook in the West Divide, a silver-lead prospect, and he is reported to control practically all of the stock with the exception of that held by L. L. Patrick. The cross-cut from the tunnel level at a depth of 150 ft. is being continued and a raise has been started. The cross-cut has passed the point where the vein should have been entered, according to the dip as indicated in the workings from the bottom of the 65-ft. inclined shaft, which cuts the vein. The vein dips east, and well west of the shaft there are two outcrops. If the most westerly of these outcrops is the vein cut by the shaft, then, according to surveys, the cross-cut at 150 ft. is still 20 ft. from the vein, and if this is true the dip is not as great as was estimated from the outcrop farther east. The cross-cut is approaching the foot-wall of the vein. Between the bottom of the shaft and the tunnel-level there is an intrusion of lime that has only a slight dip and it is also considered probable that the vein flattens and follows the lime, instead of continuing below it with a dip as indicated in the shaft workings. It is on this theory that the raise is being driven. The West Divide has become the centre of interest in Nevada because of the heavy buying of the stock on the San Francisco exchange by Mr. Kendall.

TOBAR.—One hundred tons of silver-lead ore is being hauled daily from the Spruce Monarch to Tobar and Currie, 25 miles distant. Two caterpillar tractors and eight motor-trucks are being used. The ore is being treated in Utah smelters.

EUREKA.—During the last 40 days 200 tons of ore has been shipped from the Croesus. There is a shortage of cars for shipping ore and this has been felt particularly by the Holly and Ruby Hill for two weeks.

TONOPAH.—The tailing at the Tonopah Extension, West End, and MacNamara mills was covered with a thick coating of sand during a recent storm. Lessees had prepared the ponds for sweeping and treatment in the special plant of the Belmont for this purpose. The tailing is regarded as being lost for recovery by sweeping.

STONEWALL MOUNTAIN.—The Yellow Tiger tunnel is 500 ft. long. A drill-sharpening machine is now being used. The stockholders have made a generous response to the call for assessment No. 2, according to Gordon M. Bettles, manager.

The Red Indian Metallic Point Co. has been organized at Reno to develop a deposit of red ochre, or 'paint ore', that is said to be 97½% oxide of iron. The president of the company is Charles R. Evans, Congressman from Nevada. The claims, which are five miles from the Sterlag tunnel of the Yellow Tiger, are developed by several short tunnels and shallow shafts.

NEW MEXICO

OPERATIONS AT BURRO MOUNTAIN CONCENTRATOR ARE RESUMED.

BURRO MOUNTAIN.—On August 1 operations were resumed at the Phelps Dodge Corporation's Burro Mountain concentrating plant after a shut-down of 14 months, during which time the two-unit concentrator has been completely remodeled under the direction of H. Kenyon Burch.

The original mill as completed in 1916 was designed for 500 tons per unit, but the capacity was increased by minor changes, until at the time of the shut-down 700 tons per unit was being handled. Arrangement of plant at that time was: crushing-plant, No. 8 gyratory, grizzlies, and three vertical-disc crushers followed by three 54 by 24-in. rolls breaking to four-mesh. Each unit of the concentrator consisted of six roughing-tables, two duplex classifiers, four 48 by 96-in. rod-mills, and two more duplex classifiers. The classifier sand went to six sand-tables and the slime to six mechanical-flotation machines; all flotation tailing went to fifteen pan-motion vanners. Tailing from the six sand-tables was added to the vanner tailing.

Rearrangement of the mill as it is now running to handle 1000 tons per unit is as follows: crushing-plant, 3-in. grizzly, No. 8 gyratory, two 48 by 120-in. trommels to 1½ in., two vertical-disc crushers to 1½ in. Concentrator unit, two 78 by 150-in. rod-mills, seven roughing-tables, two duplex classifiers, four 48 by 96-in. rod-mills in closed circuit with two duplex classifiers. Slime from all classifiers goes to four pneumatic flotation machines, with the flotation tailing to 24 slime-tables. Flotation feed is 48-mesh. Three No. 7½ rotary blowers furnish air at 4 lb. pressure to all of the flotation machines, which are arranged with rougher and cleaner cells, all tailing coming from the roughers. Operations were resumed without mechanical difficulty, with a certainty that concentration will yield a higher extraction than was attained in the old plant. The flow-sheet of the plant as now operating is shown on the opposite page.

Electrical transmission-lines from the power-plant to the concentrator have been doubled to take care of the extra power required. The power-plant is now equipped with four Nordberg-Carels five-cylinder vertical Diesel-type generating engines delivering a total of 5000 hp. for all mining as well as concentrating requirements. A duplicate of the 4000-cu. ft. Nordberg-Carels Diesel compressor erected in 1917 has been added to ensure a continuous and economical supply of air for mining; the power-plant is completely equipped with Diesel engines and is the largest of its type thus far erected in the United States.

During the period of reconstruction at the mill, extensive development was carried out at the mine, 122,338 ft. of work having been done, with some churn-drilling from the surface. The result was a satisfactory increase in the grade and tonnage of ore-reserves and a more economical arrangement of tracks and equipment for underground haulage.

UTAH

UTAH COPPER OPERATIONS.

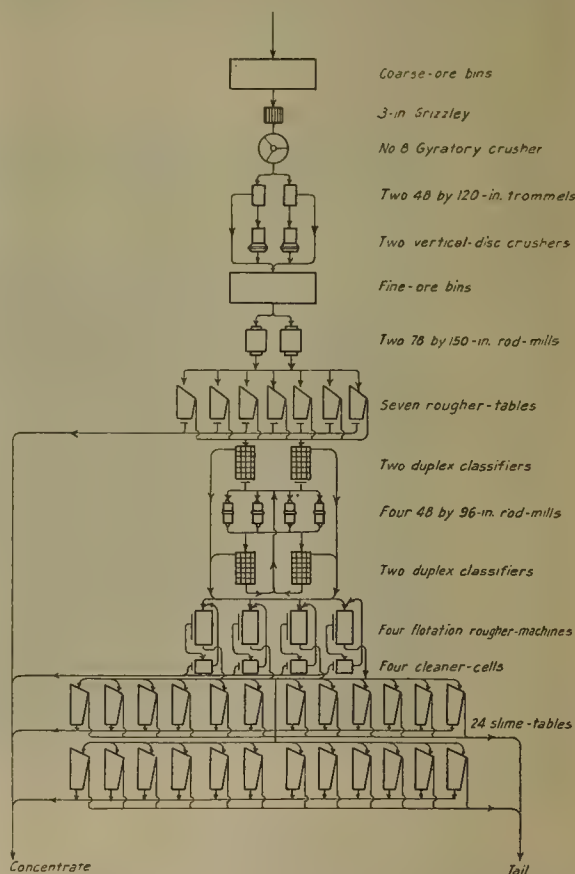

SALT LAKE CITY.—During the second quarter of the current year, the Arthur plant of the Utah Copper Co. treated 1,428,600 dry tons of ore, being 145,300 tons more than for the preceding quarter. The ore averaged 1.213% copper and the average extraction was 82.8%, as against 1.233% and 86.14%, respectively, for the first quarter of the year. The production of copper from concentrate was 28,697,127 lb. and from leaching-plant precipitate 307,254 lb., making a total of 29,004,381, as compared with 27,257,546 lb. for the first quarter. The average cost per pound of net copper produced, including all charges except Federal income tax reserve and without credit for gold, silver, and miscellaneous income, was 13.697c., as compared with 13.202c. for the previous quarter. The value of the gold and silver was \$234,544, while miscellaneous income amounted to \$300,767. These items combined are equal to 1.929c. per net pound of copper produced. The total net profit for the second quarter was \$2,240,470. A dividend of \$1.50 per share, or \$2,436,735, was paid on June 30, leaving a deficit for the quarter of \$196,265, as compared with a profit for the first quarter of \$433,855. The earnings for the second quarter were computed on the basis of 18.209c. per pound for copper, as against 21.994c. the previous quarter. The lower carrying price was due to sales of copper having been less than the quantity produced during the period, whereas during the first quarter of the year, the reverse was true. During the quarter there was removed 760,610 cu. yd. of capping, as compared with 839,713 for the first quarter. The Bingham & Garfield railway transported a daily average of 19,068 tons of freight during the quarter, as against 17,458 tons for the previous quarter.

PARK CITY.—The Park-Utah company made its first shipment in many months during the week ended August 7. The total output of the mines in this district for that week was 2308 tons, as compared with 1901 tons for the previous week. The Judge M. & S. shipped 721 tons; the Ontario, 540 tons; Silver King Coalition, 542 tons; Daly-West, 339 tons; Park-Utah, 64 tons; and Naildriver, 120 tons. The Judge smelter shipped 20 tons of premium spelter. At a special meeting of the stockholders of the Copper King Mining Co. on August 9, it was unanimously voted to consolidate that property with the Big Cottonwood Coalition Mines Co. This will give the new company about 400 acres of mineral-bearing ground. The property is situated in the Big Cottonwood district, and from recent reports indications are promising. Conditions continue to be good at the Iowa Copper property, small pockets of galena occasionally appearing in the face of the cross-cut on the 200-ft. level, according to David Scott, the manager.

EUREKA.—An offer to purchase the property of the Godiva Mining Co. has been made, and a special stockholders' meeting has been called for August 21 to consider the proposition. This is one of the old mines of the camp, and at present it is controlled by the Mc-

Chrystal interests. During the week ended August 7 the Chief Consolidated shipped 49 cars; Tintic Standard, 28; Dragon, 12; Eagle & Blue Bell, 10; Iron Blossom, 9; Mammoth, 9; Grand Central, 7; Iron King, 6; Gemini, 4; Victoria, 3; Swansea, 3; Gold Chain, 2; Centennial Eureka, 2; Bullion Beck, 2; Sunbeam, 2; Tintic Drain Tunnel, 1; Laclede, 1, making a total of 150 cars, as against 140 cars shipped the previous week.

Thomas O'Keefe has accepted the superintendency of the Griggs-Huish concentrator. Operations at the plant were started early in August, the material treated being the tailing from the May Day mill. The necessary con-

NEW FLOW-SHEET FOR BURRO MOUNTAIN CONCENTRATOR

nections to enable milling ore from the May Day and Yankee properties to be delivered direct to the ore-bins at the new plant have been completed.

During the second quarter of the current year the Chief Consolidated Mining Co.'s development work totalled 6948 ft. of drifts, winzes, and raises. There was shipped a total of 20,071 tons of ore, yielding after smelting, transportation, and sampling charges, \$407,993. The average assay of the ore shipped was as follows: gold, 0.07 oz.; silver, 25.57 oz.; lead in lead ores, 11.9%; zinc in zinc ores, 34.29%; zinc in zinc-lead ores, 16.77%, and lead in zinc-lead ores, 13.14%. The average gross value per ton of all ores was \$39.44; smelting, freight, and sampling, \$18.12, leaving a net value of \$20.32.

After payment of all charges, the net profit for the quarter was \$18,073. The cause of the large decrease in profits was the drop of 29c. per ounce in the price of silver, and the continuance of high operating, freight, and treatment costs. During the quarter there was paid out for additional mineral land about \$57,000; this payment covering several small areas necessary to protect the company in its future operations. What is thought to be an entirely new ore-zone has been cut in the eastern part of the property. For some time, two drifts, several hundred feet apart, have been driven eastward on the 1800-ft. level. Recently work has been confined to the north drift, and at a point about 1500 ft. from the most easterly known ore deposit, the new zone was found. The point where this work is in progress is about 1200 ft. from the new shaft.

According to officials of the Pinion Queen Mining Co., the treasury now contains sufficient funds to continue development work which has been in progress for some time past. The shaft is now at a depth of 730 ft., and when the 900-ft. level is reached, sinking will be stopped temporarily to permit cross-cutting and drifting.

Since the re-timbering of the main working-shaft at the Bullion Beck property was completed, seven cars of ore have been shipped. Recently some additional leases have been given. There is still considerable virgin territory at this property, although the mine has been a producer for nearly 50 years.

GRAND COUNTY.—Thirty years search for a rich gold vein has been rewarded by a discovery in Miners' Basin, about 35 miles from Moab. During that period W. I. Fowler and Robert G. Bryant have been prospecting every summer in an effort to discover the source of the rich float picked up in Miners' Basin. The find is reported to have been made in a mountain just south of the Tornado property, and the quartz ore assays as high as \$2000 per ton. Dozens of locations have been staked during the past ten days, indicating that there will possibly be a revival of the boom of twenty years ago, when Miners' Basin boasted a population of several hundred people.

WISCONSIN

NEW JERSEY ZINC CO. MOVES PLANT.

HIGHLAND.—The New Jersey Zinc Co., which purchased in fee thousands of acres of land in this district for the purpose of mining for smithsonite is abandoning the camp after heavy investments in modern plants. The big deposits have been exhausted. Seven mills are being dismantled and the machinery removed to other districts in the field where the syndicate is now engaged in zinc mining.

CUBA CITY.—The Zinc Hill Mining Co., a South Dakota corporation, licensed to do business in Wisconsin, has increased its capital stock from \$300,000 to \$1,000,000. The increased capital will provide for two new zinc-concentrating mills; an all-steel magnetic separating-plant of the Louis Skinner rabble type, to cost \$100,000; and a site for the new separating-plant. Charles Wolf,

president and manager of the Zinc Hill Mining Co., is authority for the statement that it is the intention of the company to erect a zinc-smelter at some convenient point in the coal-belt of Illinois. Drills at work over a period of a year have prospected the hills in and about Cuba City and the east extension of the Raisbeck range has been proved over a stretch of a mile. It is said this will guarantee large zinc-ore production over a period of several years. The Big Dick mine, owned and operated by the Zinc Hill, is now producing at the rate of 50 tons of zinc concentrate on a single shift in the mill. Mechanics are engaged in erecting a new 100-ton zinc-mill, on the Lee farm south of and adjoining the Big Dick mine. The principal shareholders of Zinc Hill Mining Co. are Davenport and Waterloo (Iowa) capitalists. It is stated that the company has ample financial support.

BENTON.—The Frontier Mining Co., now operating the Middle and Bull Moose mines, is dismantling and removing to a new site, near the Bull Moose mine, its 250-ton power, mining, and milling plant at the Frontier mine, where the ore has been exhausted. The Middle and Bull Moose mines are large producers of zinc ore and big reserves of milled ore are held at both mines. Rich strikes have been made by the Frontier Mining Co., on the Farrey-Whaley lands, the main deposit of zinc ore being 30 ft. thick. Drills are at work proving the Furlong farm, in Vinegar Hill township, near the site of the former Vinegar Hill mine, where outcrops of lead ore were found recently. The Frontier Mining Co. was originally incorporated under the laws of Indiana for \$75,000. Later this was increased to \$125,000; it has been one of the consistent dividend payers in the Wisconsin field.

BRITISH COLUMBIA

PREMIER TUNNEL CUTS VEIN AT A DEPTH OF 675 FEET.

STEWART.—The most important news of the week is the striking of the ore-shoot at the Premier mine by a tunnel at a point 675 ft. below the outcrop. It will take time to determine the width and length of the shoot, but the quality of the ore is said to be similar to that in the upper levels. It has been decided to erect a cyanide-plant at the mine, and this and the concentrator probably will be in operation before the end of the year. The Algonican Development Co. is pushing exploration and development at the Spider, Northern Light, and Fitzgerald groups. Next to the Premier company, which is employing more than 150 men, the Algonican company is the largest employer of labor in the district. R. P. Thompson, of Everett, Washington, has struck high-grade silver ore at the Bayview group, on the hills near Stewart. He has established a camp on the property and is cutting a trail through difficult ground that entails a good deal of blasting. R. F. Weeks, of the Consolidated Gold Fields, Ltd., of South Africa, has been examining properties in the Alice Arm district. Mr. Weeks is said to have an option on a controlling block of stock in the McLennan Mines, Ltd., which owns the Royal group, ad-

joining the Dolly Varden property on the west. He will soon be prepared to make his report.

TRAIL.—The Emma mine, which was closed at the time that the copper blast-furnaces at the smelter were shut-down, is being re-opened. A force of 50 men is at work and it is expected that six cars of ore will be shipped from the mine each week. The Emma ore contains hardly enough copper to pay for mining and transportation, but is rich in iron, and consequently useful for fluxing the silicious ores. At the time the mine was closed, it was thought the Canada Copper Corporation would be shipping concentrate to Trail before this, and that the iron content of the concentrate would supply the necessary flux for the other ores. During the last ten days of July, 12,862 tons of ore and concentrate was

instances by finding their headquarters in the hills rifled on returning from their periodical trips.

The Perrier Gold Mines Ltd., of Nelson, recently incorporated with a capitalization of \$250,000, announces that the development of the Perrier, on Cottonwood creek, will be proceeded with. The property has been opened by two shafts, one being 120 ft. deep with a northerly drift 200 ft. in length from the bottom. There are two feet of good milling ore in the shaft and a similar width in the face of the drift. The smaller shaft, 40 ft. deep, has been sunk in four feet of milling ore. The latter is said to be similar to the product of the Athabasca and the Granite-Poorman, from 60 to 70% of the gold being free-milling. While there is a considerable body of ore blocked out, no stoping has been done as yet,

BULLION BECK AND CHAMPION MINES AT EUREKA, UTAH

received at the smelter, 10,916 tons coming from the Consolidated company's mines. The other shippers were: Bluebell, Riondel, 140 tons; Caledonia, Adamant, 3 tons; Florence, Princess Creek, 56 tons; Josie, Rossland, 349 tons; Mandy, La Pas, 870 tons; Monarch, Feld, 138 tons; North Star, Kimberley, 291 tons; Providence, Greenwood, 48 tons; and St. Eugene, Moyie, 51 tons. Total receipts for the year to date are 181,157 tons.

NELSON.—The Prospectors' Protective Association continues to gather strength. Local organizations representing the Grand Forks and Smithers districts have made applications to the central body for copies of the constitution and there is every reason to believe that they will become affiliated. It has been decided that the attorney-general shall be asked what action will be taken to protect prospectors' cabins and caches from the depredations of thieves. It appears that members of the association have been put to expense and annoyance in many

the ore shipped having been taken out in the course of development. The present equipment includes a 150-ton milling-plant, a compressor, a friction-hoist, and a hydraulic pump, this being operated by water-power brought through a 2500-ft. eight-inch wooden pipe.

VANCOUVER.—John Hopp, well known as a hydraulic-placer operator in the Cariboo, states that, while British Columbians interested in this phase of mining appreciate government action in relieving them partly from taxation and the payment of royalty, they still are seriously handicapped. With camp supplies, fuel, and wages doubled in cost, the gold-mining companies are in difficulties by being compelled to market their product at an arbitrary figure. "We miners," he said, "only wish that gold would be left free to have its price fixed by the law of supply and demand. The arbitrary price of \$20.67 per ounce hits us hard. Only the best conducted plants can afford to operate and many placer men are just

holding on and not operating." He stated that the water has been late this year and that to make it worse there is a very rapid run-off which probably will limit the season to 90 days.

ONTARIO

LOW-GRADE CYANIDE IS WINNING FAVOR.

COBALT.—Low-grade cyanide manufacture by the American Cyanimid Co. at Niagara Falls is coming into general use in the Cobalt district, and to some extent is replacing the higher grade article manufactured by the Cassel Cyanide Co. of Glasgow, Scotland. The reason given for using the low-grade material is a saving in costs which more than compensates for the added inconvenience. This week it is announced that the Hollinger and the Dome, which are the two leading gold-mining companies in Canada, have each ordered a carload of the low-grade chemical with a view to carrying out detailed experiments. Arrangements have been made to explore the La Rose Consolidated ground by core-drilling, as part of a final scheme to tap all remaining prospective territory on the property. An effort will be made to commence taking ore from the Bailey Silver mine within the next month or six weeks. The Bailey mill, treating custom ore, is making from \$2500 to \$5000 net profit monthly pending treatment of the 23,000 tons of medium-grade ore estimated to be in sight at the Bailey mine.

Added activity is reported in the Elk Lake district, where the Triangle Silver Mines, Cane Silver Mines, and Parragon-Hitchcock properties are among those starting work. The Parragon has had 400,000 shares of stock underwritten and plans to install a small plant for treating its ore at the property. The Cane Silver Mines has been bought outright from its former Elk Lake owners. The La Rose Consolidated Co. of Cobalt has been asked to assist in financing the work, and a representative of this company is now examining the property.

A prosecution has been instituted against the Mining Corporation of Canada on the charge of conducting blasting operations on the Buffalo open-cut so as to endanger life and property. The neighborhood is thickly populated and it is alleged that owing to the neglect of proper precautions by the company the houses have been struck by falling rock involving serious danger to the residents. The Police Magistrate sent the case for trial to a higher court.

KIRKLAND LAKE.—The annual report of the Kirkland Lake for the year ending May 31 shows earnings of \$159,777, operating costs of \$135,278, and profits of \$24,499. Little work was accomplished during the first five months of the year owing to the miners strike. During the period from January 1 to May 31 the mill handled something over 100 tons per day or two-thirds of its capacity, mill-heads during May averaging \$12.03 per ton. On March 1 it was estimated that between the 300 and 700-ft. levels there was 120,000 tons of ore in sight, enough to keep the mill running at capacity for over two years, and later development proves that the orebody extends above the 300-ft. level, adding materially to this estimate.

The new mining plant of the Hunton-Kirkland has been completed and will be put in operation this week. Extensive development has been planned. The main shaft will be put down to a depth of 300 ft., at which point the first lateral operations will be started.

GOWGANDA.—A number of the companies operating in this camp have suspended work for the present, owing to the high cost of labor and supplies and the decline in the price of silver. Some of the companies are waiting for the construction of the light railway, the route for which has been surveyed for 20 miles, before resuming operations. The directors of the Big Four, who recently visited the property, have decided to employ oil-burning engines, as a means of overcoming the fuel difficulty. The company owns about 155 acres, comprising a large hill of rock, containing a net work of veins running in different directions. From the top of the hill a shaft has been sunk 40 ft. finding ore worth about \$26 per ton, and a tunnel has been run into the side of the hill. In addition to silver the ore carries a large amount of cobalt. A vein 22 ft. wide, stated to carry 44% sulphur, has also been found and will shortly be opened up.

YUKON TERRITORY

THE MAYO DISTRICT.

DAWSON.—George P. Mackenzie, gold commissioner, recently returned from the Mayo district reports activity there. W. E. Cockfield and party, of the Canadian Geological Survey, have pitched camp near Keno hill, about ten miles from the Yukon Gold Mining Co.'s camp, and are busily employed in their investigations. Surface prospecting, which cannot be done during the winter, is being given most attention, with a view to finding suitable locations for the coming winter's work. The Yukon G. M. Co. has 20 men employed at this kind of work. The ore that was taken out by the company during last winter is being hauled to Mayo. Ore is being sacked from surface work on the Rico claim, where slabs of dense argentiferous galena weighing up to 1200 lb. are being found. Erickson & McKay have uncovered a four-foot vein of galena, which gives considerable promise. Mr. Mackenzie thinks there is sufficient ore in sight to provide work for the next two years with prospects for finding entirely new deposits.

It is hoped that there may be established this summer the continuity of the ore to a sufficient depth to ensure the permanence of the camp, and diamond-drills are being used for this purpose. When this has been demonstrated, the Government must provide proper means of transportation; present conditions being bad. Some veins with the best-looking surface indications have pinched out at comparatively shallow depths. Surface outcrops, however, have been demonstrated over such a large area that there will be much prospecting during this summer, followed by development during the winter, and it is thought that a reasonable proportion of the lodes will be found to persist to a sufficient depth to make mining profitable and to encourage the Government to construct the much-needed roads.

THE MINING SUMMARY

MINERALS SEPARATION LITIGATION

The Nevada Consolidated Copper Co. has admitted openly that it has infringed that patent of the Minerals Separation North American Corporation governing the use of oil in flotation in amounts less than 1% on the ore. This admission was made before Judge Hale in the U. S. District Court in Portland during discussion of a motion requesting further answers to interrogatories in connection with the infringement suit of the Minerals Separation Co. against the mining company. The period of infringement extended from September 1914 to August 1917 when flotation was used in Janney machines.

Suit of Mineral Separation Co. against the Magma Copper Co. has also proceeded another step, although the latter's motion for a bill of particulars has been denied. In this instance Judge Hale said: "It appears . . . an attempt to force from the complainant a statement of what his endeavor is to be upon certain material allegations in the bill. . . ." The litigation with the Magma company, as with Nevada Consolidated in the same court, has to do with two patents, one for the use of less than 1% oil and the other covering soluble frothing-agents. As matters now stand, each defendant must file before October 1 answer to the Mineral's Separation's bill of complaint. Suit against the Miami Copper Co. has been held up temporarily by the refusal of the Wilmington court to permit Minerals Separation to file a supplemental bill of complaint alleging further infringement and seeking an injunction for alleged contempt of court. The court in this case has demanded an entirely new suit be started unless the present case can be threshed out before the master who has been engaged for more than a year taking testimony for an accounting.

CALIFORNIA

Amador County.—Drifting in several directions is in progress on the 3500-ft. level of the Old Eureka, and 1500 ft. below the old workings. The latter part of the sinking was in soft rock, and good progress was made.—Sinking to the 3900-ft. level at the Central Eureka is completed, a station has been cut and levels will be started immediately.—All ore taken out of the 600-ft. winze in the Bunker Hill mine near Amador City is of too low grade for treatment, assaying not over \$3 per ton.—Operations at the Keystone mine in Amador City have come to a standstill after the collection of two assessments. The plan of keeping the mine dry pending a change in conditions was found to be too expensive, so the mine is filling up. The cost of unwatering will be much less than the other procedure.

The Argonaut company continues to hoist and pump water, but the headway made is slow. It has been estimated that 190,000,000 gal. flowed into both mines in order to extinguish the recent fire. The Argonaut and Kennedy mines make 150,000 gal. in 24 hours. The former company has three No. 9 Cameron relay pumps, operated by compressed air, raising water to the 2000-ft. station, and from there an electrically driven Deane pump forces it to the surface. About 350,000 gal. is raised daily. The present water-level is just below 3300 ft. There have been persistent rumors of the Kennedy starting and also of a sale to the Argonaut people, but neither can be verified here. The Kennedy is

idle in every department.—At a recent meeting of the Board of Equalization the assessment on the Argonaut M. company was reduced from \$508,410 to \$334,155, the Original Amador from \$15,000 to \$12,500, the Central Eureka from \$172,000 to \$106,890, and the Old Eureka from \$65,125 to \$50,000.

Nevada County.—Peter Delucci is building a two-stamp mill on his claim about two miles above Graniteville.—J. T. Blight and others have taken a bond on the Delhi a few miles above Nevada City, and are preparing to develop the property. H. E. Sayers of Pasadena is making an examination.—W. A. Simkins has taken over all interest of Jack Harris in the Lily mine on the Mitchell ranch near Grass Valley. The Western Precious Metals Corporation has had the mine under development until recently and Simkins states that work will be resumed under his management.

Sierra County.—Joseph Mason and F. T. Meadery are making preparations to mine the East Fork of the North Yuba river half a mile above Downieville. The ground has never been worked.—Water has been drained from the 300-ft. shaft in the Gibraltar gravel claim near Downieville and when re-timbered the ground will be explored to learn the course of the channel.

IDAHO

Coeur d'Alene.—The Federal Mining & Smelting Co. is hoisting 900 to 1000 tons daily from its Morning mine, and shipping 3500 to 4000 tons of crude ore and concentrate monthly, according to Frederick Burbridge, general manager. About 425 men are employed. A raise is being made from the North Star tunnel level to the Independence tunnel-level, a distance of 450 ft. The work is being done in country rock, and it is expected to be completed within a month. The purpose of the raise is to provide an outlet to the North Star for ore from the Independence. All ore broken in the Independence will be removed through the raise and tunnel, and dressed in the North Star mill. Shipments from the Independence mine aggregate about 1000 tons monthly.

Three shipments made by the lessees in the lower workings of the Monarch mine in the North Fork district have netted good returns. From the three shipments \$1178 was returned for 16 tons, \$3067 for 38 tons, and \$2668 for 45 tons.—Good indications are reported in the face of the tunnel being driven by the United Lead Mining Co. in the North Fork district. It is expected that within 80 to 100 ft. the drift will reach the orebody shown in the tunnel above. A. M. Nash is manager.—Eighteen men are employed by the Jack Waite mine. The company is using two trucks to haul the ore and has ordered two more. Two carloads have been shipped to the smelter.—A controlling interest in the Kill Buck Mining Co. has been purchased by the Chicago-Boston, which company recently acquired an interest in the Callahan Zinc-Lead company. The purchase is an important one, adding materially to the holdings of the Chicago-Boston. Some years ago ore was sold for \$80,000, but the shipments seemed to exhaust the ore in sight and it has been a geological puzzle to know where the orebody is.—Louden and Lane, who have been developing a group of claims near the divide between the head of the main fork of

Pine creek, say they have cut their vein at a depth of a little more than 100 ft. They report an orebody 2 to 3 ft. wide of galena ore with some copper.

UTAH

Bingham.—A serious accident occurred at the Utah Copper mine on the morning of August 13. Mine locomotive No. 14, while pushing a flat-car on which 10 Japanese laborers were riding, was struck by locomotive No. 29, coming down from one of the upper levels with 7 cars of ore. Two of the Japanese were killed instantly, and the third died within a short time, while the remainder of the party sustained minor injuries.

Washington County.—Sydney H. Ball, of New York, has been making an examination of the Silver Reef Consolidated property at Leeds. This property is to be developed by a syndicate headed by Frank T. Moorehouse. Mr. Ball expressed himself as favorably impressed with the project.

AN INVITATION TO TECHNICAL ORGANIZATIONS

The Joint Conference Committee of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, acting as an ad-interim committee in accordance with the authorization of the organizing conference held in Washington, D. C., June 3-4, 1920, extends to your organization a cordial invitation to become a charter member of the Federated American Engineering Societies, and to appoint delegates to the first meeting of the American Engineering Council, of which due notice will be given later.

There has been previously sent to you an abstract of the minutes of the organizing conference, at which there were in attendance 140 delegates, representing 71 engineering and allied technical organizations. It was the unanimous opinion of the conference that there should be created an organization "to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern in the engineering and allied technical professions" and that this organization should consist of societies or affiliations, and not of individual members.

At the gathering in Washington, which was the greatest event in the history of the engineering and allied technical organizations in this country, steps were taken which created 'The Federated American Engineering Societies', which will have a far reaching influence on the future of these professions. The fact that this action was taken without a dissenting vote indicates that the psychological moment had arrived and that there was a unanimous desire on the part of the representatives of these professions for the organization formed.

The Joint Conference Committee, the ad-interim committee, would ask each organization invited to take favorable action in the matter of membership in the organization at the earliest possible moment and to advise the Committee promptly of the names of the delegates who will attend the first meeting of the American Engineering Council in November of this year.

The Joint Conference Committee is confident that with the universally acknowledged need for such an organization, there will be a prompt affirmative response to this invitation.

Very truly yours,
JOINT CONFERENCE COMMITTEE
of

American Society of Civil Engineers
American Institute of Mining and Metallurgical Engineers
American Society of Mechanical Engineers
American Institute of Electrical Engineers.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Wendell T. Jones, of Salt Lake City, is in San Francisco.

Eugene G. Snedaker is in Denver, on his way to New York.

Herbert W. Pudan has returned from Mexico to San Francisco.

Fred B. Ely, of Fort Worth, Texas, was in San Francisco for a few days.

Milton F. Dodd, foreman of the Benguet mill, is on his way back to the Philippines.

Roscoe H. Channing, president of the Utah Consolidated Mining Co., is at Salt Lake City.

Frank A. Wicks is making an examination of the Glove mine, in Santa Cruz county, Arizona.

E. H. Clausen has returned to Berkeley from professional engagements in Colorado and Nevada.

L. J. Ingolfssrud, engineer for the Santa Gertrudis Co., at Fresno, Mexico, has moved to El Paso, Texas.

Arthur F. Taggart, professor of ore dressing at Columbia University, has been in Utah on professional business.

Raymond Bassett, chief engineer to the American Brass Co., has been visiting mining and metallurgical plants in Utah.

C. W. Newton, general manager for the Con. Interstate Callahan Mining Co., has returned to Wallace from New York.

E. W. Engelmann has returned to Salt Lake City, after a short trip to the Nevada Con. Copper Co.'s concentrator at McGill, Nevada.

J. Benton Leggat, general manager for the Argyle Silver Mining Co., of Montana, has returned to Salt Lake City from St. Louis.

F. C. Calkins, of the U. S. Geological Survey, is now in charge of a party surveying the mines of the Cottonwood mining district in Utah.

K. D. Koliashnikoff, until recently resident manager of the Kyshtim Corporation in Siberia, is in Utah, visiting mining and metallurgical plants.

Victor C. Alderson, President of the Colorado School of Mines, has returned from Scotland and England, where he investigated the oil-shale industry.

C. N. Shuette, recently superintendent of the Mariscal quicksilver mine, in Texas, has re-joined the staff of the U. S. Bureau of Mines at Berkeley.

Otto Sussman, vice-president of the American Metal Co., has returned to New York after a visit to the company's properties at Baxter Springs, Kansas.

George A. Laird, who has just returned to New York from Mexico, has been appointed general manager for the Guiana Development Co., and will leave for South America in September.

Charles H. Fulton has resigned the professorship of metallurgy in the Case School of Applied Science, at Cleveland, in order to accept the directorship of the Missouri School of Mines, at Rolla.

Ralph R. Woolley, hydraulic engineer to the U. S. Geological Survey at Salt Lake City, is investigating electric power-generating possibilities of the headwaters of the Green river in Wyoming.

Robert S. Lewis, Professor of Mining and Metallurgy in the University of Utah, has been appointed by the U. S. Bureau of Mines to conduct a six weeks investigation of copper deposits in Alaska. He expects to return to Utah early in October.

THE METAL MARKET

METAL PRICES

San Francisco, August 17

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	19.35
Lead, pig, cents per pound.....	9.25-10.25
Platinum, pure, per ounce.....	\$115
Platinum, 10% Iridium, per ounce.....	\$165
Quicksilver, per flask of 75 lb.....	\$85
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

August 16.—Copper is inactive but firm. Lead is quiet but strong. Zinc is dull but higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

CALL LOANS

With the exception of bankers and brokers and those who invest their surplus funds in market securities, most people seem to have a general misunderstanding of the laws and customs governing the various charges for the use of money. There is, however, sufficient justification for much confusion, when on the same day in New York City, discounts to a bank's customers are quoted at 6%, commercial paper in the open market at 7%, banker's acceptances at 5 1/4%, call loans at 25%, and collateral time-loans at 8%. Probably the one item which has caused the most confusion during the recent months of high money is the call-money rate. When people see 30% money, for example, featured in the newspapers, there is a general feeling that the banks are doing a little profiteering and would stand investigation along the lines which have recently been prevalent in other businesses, says the 'Chemical Bulletin' of the Chemical National Bank.

Probably the only call-money market of national importance is in New York City, and it is there that collateral call loans are chiefly made. These loans are secured by pledge of investment securities, usually stocks and bonds dealt in on the New York Stock Exchange, and payable on demand of the bank or lender without previous notice. It can thus be seen that these loans are in an entirely separate class from those made by a bank to its commercial customers or depositors for usual business purposes. The claims of such clients have the first place in the eyes of the banker, not only in New York but in all cities, and it is only therefore the banks' surplus funds which are loaned on the Stock Exchange at call-money rates. The excess of loanable funds available for employment in this manner varies according to the country's commercial needs, which always have first consideration.

It is of course evident even in times of great stringency that some money must be loaned to finance the purchase and sale of investment securities, for if the investment market were at a standstill for lack of funds, commercial customers would suffer as well.

Since the position of call loans as compared with commercial borrowings has now been discussed, the legal aspect of the question is interesting. Most call loans are made in New York City, as stated before, and upon examining the Banking Law of New York State we find that Section 115 provides that "Upon advances of money payable on demand to an amount not less than \$5000, made upon warehouse receipts, bills of lading, certificates of stock, certificates of deposits, bills of exchange, bonds or other negotiable instruments, pledged as collateral security for such re-payment, any bank may receive or contract to receive and collect as compensation for making such advances any sum which may be agreed upon by the parties to such transaction."

The rate for which call money is loaned by the banks is of course based largely on supply and demand. "The old axiom, which applies to money in general, that "a temporary increase of the money supply in excess of the demand tends to lower the rate of interest temporarily, and a temporary decrease of the money supply, the demand not also decreasing, tends to cause the rate of interest to rise" is largely true in the case of call money.

MONEY AND EXCHANGE

Foreign quotations on August 17 are as follows:

Sterling, dollars: Cable	3.85
Demand	3.86
Francs, cents: Cable	7.39
Demand	7.40
Lire, cents: Demand	5.05
Marks, cents	2.17

Eastern Metal Market

New York, August 11.

Mid-summer dullness pervades all the markets and there is very little business recorded in any of the metals. There are no indications of increased buying due to anticipation of higher freight rates.

The copper market is quiet but firm.

There is almost no business in tin.

Demand for lead has declined but prices are steady to firm.

There is no change in the zinc market which continues lifeless.

The antimony market is without quotable change.

IRON AND STEEL

The feature of the market as to buying-demand is the activity in pig-iron. The demand for iron, particularly steel-making grades, is perhaps more pronounced than at any other period this year. Consumers' demand is for both nearby and distant delivery. In the East it is said that over 50,000 tons of foundry, basic, bessemer, and malleable iron was sold recently.

The semi-finished steel market in Pittsburgh is easier with steel bars down to \$79, and nothing higher than \$75 has been heard of. A marked decline is not looked for because of increased costs due to higher freight-rates and resulting costs.

The July output of steel ingots was 2,802,818 tons according to the American Iron and Steel Institute's regular figures. This is the second lowest for the year. The total to August 1 this year has been 20,436,252 tons against 17,370,556 tons to August 1, 1919.

COPPER

This market is practically without change as to demand or prices. The leading producers continue to hold their price at 19c., New York, for both Lake and electrolytic. Domestic demand is confined to small lots for fairly early delivery and it is probable that these are being satisfied by outside dealers or small producers at 18.50 to 18.75c., New York, at which levels only small quantities are available. The fall in exchange the past two weeks has caused sales for foreign account to diminish. Indications are that copper output in July declined. Twelve of the largest producers have given out their figures and eight of them show a combined loss of over 5,000,000 lb. for June. The London market on standard copper, while showing increased business, eased off yesterday 5s. per ton on all positions.

TIN

The marked decline in foreign exchange, particularly the pound sterling, has had a distinct effect on the tin market as well as some influence on all the metals. The principal factor, however, has been the absolute lack of demand, consumers being entirely out of the market. Yesterday the metal was weak, declining about one cent per pound to 48c. New York for spot Straits, nearby futures being quoted at 48.25c. There was some willingness by sellers to make concessions, but it was without results, although there were some inquiries in the market on Monday. As a result of these conditions the market has been lifeless all the week, with the price-range confined to 48 to 49c., New York, for spot Straits. Yesterday the London market was £295 per ton for spot Straits against £288 a week ago. This grade is quite scarce in both markets. Business on the New York Metal Exchange has been light this week.

LEAD

The market is dull. It is, however, statistically strong

because of the continued scarcity of nearby deliveries, although this condition has eased to some slight extent. The American Smelting & Refining Co. maintains its price unchanged at 8.25c., St. Louis, or 8.50c., New York. All the business done here being by outside sellers at around 9c., New York, or 8.75c., St. Louis, which we quote as the market. There have been some sales, however, as high as 9.10 to 9.20c., New York. The import lead reported to be headed for New York from England has not yet been a factor.

ZINC

Prime Western for early deliveries is unchanged at 7.80c., St. Louis, or 8.15c., New York, the latter being largely nominal. Sellers' offerings are light, and not much activity is reported. The business of leading producers is confined to business on contract and to hand-to-mouth orders. Zinc ore continues strong at \$46 to \$47.50 per ton with as high as \$53 paid in some districts. There is little if any profit for most producers at these levels and they are confining their business to nearby shipments and regular customers. There is nothing heard about the effect of increased freight rates.

ANTIMONY

The market is very quiet and quotations for wholesale lots for early delivery are unchanged at 7.25c. per lb., New York, duty paid.

ALUMINUM

The virgin metal, 98 to 99% pure, is quoted in wholesale lots for early delivery at 33c. per lb., New York, by the leading producers and at 31.50c. per lb. by other sellers.

ORES

Tungsten: There is little activity in this market. Inquiry and sales are both light and quotations are unchanged from those reported a week ago, that is, from \$5.50 per unit up, depending on the grade and the quantity as well as the delivery.

The ferro-tungsten market is quiet and unchanged at 80c. to \$1.15 per lb. of contained tungsten.

Molybdenum: There is no change in conditions with demand light and prices nominal at 65 to 75c. per lb. of MoS₂ in regular concentrate.

Manganese: The market is quiet and stale with 75 to 80c. per unit asked for high-grade ore and 70c. the highest that users are willing to pay. There appears to be an ample supply because of the heavy importations of the last few months.

Manganese-Iron Alloys: The ferro-manganese market is quiet with demand confined to small lots for early delivery, sales of which have been made at a range of \$200 to \$225. The forward-delivery market is fairly firm at \$200, delivered. The production in July, according to the blast-furnace reports of 'The Iron Age', was 29,864 tons, or the largest for any month this year. The spiegeleisen market is exceedingly strong at \$80, furnace, with demand good. The production in July was 6925 tons, relatively a small output.

There has been a definite change for the better in the market for silver and it is believed that we have passed the period of depression. Demand is still not of very large magnitude; but the optimism in the market is justified, says Srinivas R. Wagel, 33 Pine street, New York. An important development is the premium for forward in London, where prices are being maintained by the Indian demand. China is also reported to have bought small lots in London. There has been a material improvement in the local market; demand for arts is increasing, especially as no purchases have been made for the past two months. The total of the Treasury purchases now amount to 10,000,000 ounces.

CORNISH MINING 295

Depressed condition of the industry. Efforts to obtain aid from the British government. Failure to do so. Remarks by Oliver Wethered, chairman of Cornish Chamber of Mines. The market for tin. Condition of Dolcoath and other mines. Recent discoveries. What William Pryce had to say a hundred years ago.

A WESTERN ENGINEER 295

An appreciation of Albert Burch, apropos of the interview printed in the same issue. Early education and beginning of his career. From railroad surveying to mining engineering. Side-lights on his character. A hard worker. Testimony of associates. His interest in the men under his management, at Kellogg, Goldfield, and Plymouth. The future for young men in mining.

DISCUSSION

MR. SULMAN AND THE MEDAL

By C. McDermid 297
Reason for the action of the Institution of Mining and Metallurgy, according to its secretary.

MINING NEAR JOPLIN

By Edgar Z. Wallower 297
Labor conditions and transportation difficulties that dictated the recent suspension of operations.

MORE BOOKS WRITTEN IN A HURRY

By Max von Bernewitz 297
Some quotations from 'The Making of Herbert Hoover' in the 'Sunset' magazine. Criticised as inaccurate.

THE STATUS OF GOLD

By F. A. Wright 298
A 'Gold-Producers Bank' as a means by which the miners, instead of the bankers, may reap the profit.

CONCERNING SILVER

By Frank L. Sizer 298
Support for the plan of Charles Butters. The Mint should exchange coin for silver bullion.

THE OIL-SHALE INDUSTRY

By David E. Day 298
Exception taken to the plans of Martin J. Gavin. Let us face the situation frankly.

INDUSTRIAL PROGRESS 323

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 3514 Woolworth Bldg.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

No job too big—No job too small

THE range of the oxwelding flame is one of the marvels of modern science.

This small jet of concentrated heat is used on mammoth castings of tremendous weight as well as upon the tiniest of parts.

Whatever the size of the job, Oxweld does the work and does it better, quicker, and cheaper than was possible before the Oxy-acetylene torch came into being.

A process so flexible in its usefulness as to handle with equal success tons or ounces may very probably be applied to your own production problems to your profit.

Hundreds of manufacturers have found Oxwelding a labor, time and money-saver.

Why not ask Oxweld Engineers to study your repair or production problems?

Write, wire or telephone to any of the addresses below for immediate attention.

WORLD'S LARGEST MAKER OF EQUIPMENT FOR OXWELDING AND CUTTING METALS

T. A. RICKARD, - - - Editor

UNDER 'Discussion', we publish a letter from the Secretary of the Institution of Mining and Metallurgy explaining that the gold medal of that society was given to Mr. Sulman not on account of his recent paper on flotation but "in recognition of his contributions to metallurgical science". We accept the apology!

TO the Canadian Department of Mines we are indebted for the description of the Knee Lake district in Northern Manitoba. This part of the North-West does not seem to be particularly promising, but it is well to place on record the sort of information that would be useful to anyone desiring to prospect in that region.

IN fairness to Dr. Alderson and ourselves, we draw attention to a typographic error in our last issue, where the yield of oil from Scottish shale is given as 20 barrels; and from American shale, one half of that. The first figure, of course, should be two, as is indicated by the subsequent references to a yield of one barrel from American shale.

PERSISTENCE of rich ore in depth at Butte is indicated by the fact that the bottom of the Steward shaft is in a vein six feet wide that assays 8 to 10%. The valuable mineral is bornite. This is at a depth of 3750 feet. Whether due to primary deposition or secondary enrichment, it is highly satisfactory to note this promise of a long life for the mines of the Butte district.

IMMIGRATION is increasing. More than 5000 arrivals per day are being recorded at Ellis island, says the Department of Labor. Despite unfavorable conditions, 800,000 immigrants have landed during the twelve months ending on June 30, as compared with 141,132 during the corresponding period immediately preceding. The record was made in 1907, when 1,285,389 landed on our shores. We welcome this resumption of immigration on a large scale, provided the newcomers are scrutinized with care, so that only material suitable for citizenship is admitted.

ZINC stocks in the hands of the smelters on June 30 amounted to 29,892 tons only, as compared with 36,793 at the beginning of this year and 59,651 tons on June 30 of last year. This shows a 50% decrease in stocks during the twelve months, and is decidedly reassuring, for even in normal times a surplus of 35,000 tons

is not unusual. Eighteen months ago the market was staggering beneath the big stock of zinc accumulated at the mines and smelters under the stimulus of war prices. The surplus at that time was as much as 75,000 tons, and constituted a real menace to current production. Since then operations at the mines and smelters have been severely curtailed, so that on June 30 last only 95,000 retorts were in action as against 107,500 on January 1. Later, strikes and shut-downs have caused a further contraction in the scale of operations. Export business is insignificant, and is likely to continue a negligible factor.

LAST Friday Mr. David P. Barrows, president of the University of California, gave the Commonwealth Club the impressions he brought home from his recent visit to Europe. He made them vivid to his audience. Among other things he spoke of the work of feeding the under-nourished children of Europe as it is conducted now by Mr. Hoover's organization, more particularly in Vienna. The administration of the funds placed in Mr. Hoover's hands by the United States is so efficient that the overhead expenditure is barely 1%. What a model to other organizations for charity! Here we may mention how instant is the applause elicited in any assembly of intelligent people by the mention of Mr. Hoover's name. It is safe to say that the appreciation of his work in Europe, and in his own country, goes far to measure the intelligence of an audience. In speaking of the present sad plight of Europe, and of America's vital interest in the preservation of European civilization, Dr. Barrows referred to the aid to be given by our "reserves of trained young men". Yes, that reserve is, or can be made, as valuable to the countries devastated by the War as our reserves of capital or food, if it is accompanied by intelligent sympathy, not the vacuous aloofness advocated by Senators Borah and Johnson.

SEMI-OFFICIAL statistics issued at Berlin give the total German loss of life in the War as 2,243,364. This includes both army and navy. The army lost 1,718,608 in dead and missing. Again we are reminded of an appalling feature of the War, namely, that the Germans killed nearly twice as many as they had killed on their own side. The British lost nearly a million, the French 1,350,000, the Russians at least 1,000,000 in their fighting with the Germans. That makes about 3,250,000 deaths in the armies of the three Allies. Deducting losses against the Turks and Bulgarians from the British and French totals, and making a similar deduction for German losses

in fighting the Americans, Italians, Serbians, and Rumanians, we arrive at the horrible conclusion that the Germans suffered only half as much as the French and British combined. The disparity in lethal destructiveness probably was most marked in the early period of the War when the Germans were relatively better equipped with death-dealing devices.

CONSUMPTION of gasoline in the United States during the first five months of the current year has been 26% more than it was in the corresponding period of last year, according to the U. S. Bureau of Mines. The total consumption was 1,418,534,063 barrels as against 1,127,879,649 barrels in the like period of 1919. Of our imports of crude oil in the fiscal year ending June 30, 2825 million gallons, out of a total of 2826 million gallons, came from Mexico. We imported a million gallons of crude oil from Trinidad and Tobago. We exported over 354 million gallons of crude oil, of which Canada took 308 millions. We also exported 690,859,418 gallons of refined oil, besides 205,057,450 gallons of bunker-oil laden on vessels engaged in foreign trade. We imported 81,888,904 gallons of refined oil. Of the refined oil, Great Britain took 205 million gallons, and Canada 146 millions. Our exports of crude oil increased 190 million gallons over the fiscal year 1919, whereas our exportation of refined oil decreased by 208 million gallons.

BOOKS are written in a hurry sometimes; for example, on the eve of a Presidential campaign. Mr. Max von Bernewitz writes with a good deal of feeling to protest against some careless statements appearing in the story of Mr. Herbert Hoover's life as printed in the 'Sunset' magazine. Of course, the suggestion that Mr. Hoover or anybody else from the United States introduced the single-hand drilling practice into Australia is ridiculous; it was introduced into Australia, and into California, by the Cornish miners before Mr. Hoover was born. If Mr. von Bernewitz waxes wroth, it is due partly to the fact that he is a New Zealander by birth and is solicitous for the reputation of the Australasian mining engineer. Of course, the Hoover stories written by Messrs. Vernon Kellogg, Charles Field, and others far less competent, have contained many exaggerations, provoked by their enthusiasm and condoned by their lack of knowledge concerning the technology of mining. The pity is that these writers did not submit their manuscript, if not to their victim, at least to some competent mining engineer, and one acquainted with Mr. Hoover's career in foreign lands. The typewriting incident in the office of Louis Janin, as related by Mr. Kellogg, for example, is entirely apocryphal. The fact is that Mr. Hoover has done so many big things well that no exaggeration is needed in order to make a good story. That by Miss Lane and Mr. Field is much the best. We have read it with keen pleasure, particularly the account of his parentage and childhood. His origin and rearing are truly American, and go far to explain the personal characteristics of the most distinguished of living Americans, a man who proved

himself the most useful man in the world during the great crisis of civilization.

HOW much money is being diverted from necessities to the creation of luxury in these days is suggested by an item in the New York 'Times' stating that in July plans for only one apartment house and one dwelling were filed in Manhattan as compared with plans for five theatres, 115 garages, and three loft structures, indicating that the urgent need for adequate housing is being neglected in favor of facilities for joy-riding and entertainment. Normally New York adds 20,000 apartments per annum, in addition to two-family houses and hotel apartments. Similar conditions obtain in San Francisco and its suburbs; there is a great lack of the small houses that make homes for young people. To this deficiency must be added the tremendously increased cost of domestic service, which now has risen to such a point as to make it almost prohibitive for a young couple on a small income to have a servant, thereby throwing a burden on the mother that threatens the very foundations of a progressive people. The ideal of a civilization like ours is a comfortable and well ordered home; without it a young married man is heavily handicapped; without it the production and development of good citizens is rendered difficult, if not impracticable. It is a curious thing that these basic factors in the welfare of the commonwealth are habitually disregarded.

MECHANICAL ventilation for the 29-foot twin tubes that are to constitute the new vehicular tunnel connecting Manhattan with Jersey City will be supplied by 65 electrically driven blowers, which will be capable of completely changing the atmosphere every two minutes. The longest span between ventilating shafts is 3800 feet, while the length of the entire tunnel from entrance to exit is to be 9425 feet. It is to be noted that the traffic through the tubes will be almost exclusively by motor, although at the outset horse-drawn vehicles will be permitted to use them. Research conducted by the U. S. Bureau of Mines at Yale University established the fact that the only substance in the exhaust of a gasoline engine that is toxic to an appreciable degree is carbon monoxide. This is also the dangerous product from the explosion of the dynamite used in metal mining, and for this reason the investigation by the Bureau was particularly appropriate. It was demonstrated that four parts of carbon monoxide mixed with 10,000 parts of air produces no harmful effects on the human system during an exposure of one hour; six parts may cause slight discomfort, but eight parts of carbon monoxide are required to be really injurious. Since the maximum time for the slowest trucks to pass through the tubes is 45 minutes, complete safety will be assured if the maximum contamination is limited to four parts in 10,000. This work by the Bureau has been the means of reducing the cost of mechanical equipment as originally planned by 25%, with a corresponding saving in operating expense. Some of the blowers will force fresh air into the tubes while the

remainder will act as suction-fans for withdrawing the foul air, the two principal stations being placed on piers at either side of the navigating channel. One of the important factors in determining the diameter of the tubes was the cost of ventilation. The annual outlay for power required by the 29-foot tubes is estimated at \$280,000, whereas tubes 27 feet in diameter would have entailed an expenditure of \$529,350 for electric current. The fresh air is introduced in the sector of the tube beneath the traffic-way while the contaminated air is withdrawn through gratings into the passage above. For economical operation, the tubes must be proportioned so that a tendency for 'wire-drawing' may be avoided. This has been accomplished by the 29-foot design. These tubes will be the longest, although not the largest, in existence; they will be lined with cast-iron; they will cost \$28,670,000; the project will be completed in 1924; and ten years later the tunnels, it is estimated, will be used by 12,900,000 vehicles annually, or 3500 per day.

Cornish Mining

The mining of tin in Cornwall is in a parlous state. Therefore efforts have been made recently to obtain the aid of the British government in behalf of the industry. A representative deputation, according to 'The Mining World', waited upon the president of the Board of Trade with a plea for financial help in the development of new mining enterprises. The reply was that no public money was available for the purpose and that it was advisable for the necessary funds to be subscribed privately. The answer of the Government is not at all surprising, nor do we believe that a governmental dole is the proper stimulant for a decaying industry. Mr. Oliver Wethered, the president of the Cornish Chamber of Mines, sounds the right note when he says, according to 'The Financial Times', that he is firmly determined to make no further effort to move the Government to re-consider its decision, but that he is "more than ever convinced that there is a great future for Cornish mining". Mr. Wethered's cheery optimism, plus the force of his engaging personality, have been greatly influential in Cornish mining affairs during the last decade, and we feel sure that his leadership is one in which the 'old county' can place implicit trust. Of course, the fall in the price of tin, together with the increasing cost of labor and supplies since the War, has been a great blow to Cornish mining. In 1918 tin was worth £400 per ton; in June the price was £235. The doyen of Cornish mines, Dolcoath, is looking 'poorly' in the bottom, but East Pool, South Crofty, Geevor, and Levant are in vigorous health. As the editor of the Bulletin of the Canadian Mining Institute says: "There are many in all parts of the world who would regret the passing of this historically interesting mining centre. Directly and indirectly, the mines of Cornwall have contributed enormously to the advance of mining practice in all parts of the world." Yes, indeed, the 'Cousin Jack' has been the real professor of mining to many peoples. When it comes to working in hard rock

and in tight places, there is no one like him. He has penetrated to the uttermost parts of the earth and left his mark in every corner. From him the Phoenicians bought tin in B. C. days and to him the world will look for tin, and other metals, in the years unborn. That old worthy, William Pryce, writing in 1778, said: "Supereminently this little province of Great Britain deserves to be ranked amongst the first principles of this island, as a nation and people, whose very name, according to the ancient authority of Bochart, and the later opinion of Boerhave, is derived from Bratanak, which, in the Phoenician language, signifies the Land of Tin." After citing various authorities, he states: "We may, hence, conclude it very probable, that this part of Great Britain was the first resorted to by the most ancient maritime powers in Europe and Asia, on account of its valuable, beautiful, and precious Metal; and therefore gave a name to the whole island, with some little variation, it retains to this day, and proves the antiquity, locality, and superiority of our product, and its universal supply for the use of mankind." From Dr. Pryce's 'Mineralogia Cornubiensis', from which we have been quoting, we get an idea that is pertinent to the immediate subject, namely, the decay of the industry. He says: "We hope the land-owners will hold us excusable when we assert upon the clearest conviction that they contribute by their heavy exactions to deprive the industrious adventurers of too large a proportion of that profit which ought to be applied to the encouragement and reward of their arduous and expensive undertakings." Of course, a detached observer in California is not likely to know much about conditions in Cornwall, but it is a fact that we have heard or read somewhere that the 'lords', or landlords, around Camborne and Redruth do take too large a proportion of the profit that ought to go to the adventurers, or shareholders, and we suggest that one way to encourage the resuscitation of the Cornish mining industry is to persuade, not the Government, but the landlords to forego some of their perquisites in order not to kill the goose that lays their golden eggs.

A Western Engineer

In this issue we resume our series of interviews with representative members of the profession. Our victim this time is Mr. Albert Burch, who embodies the best traditions of Western mining. He was born in the prairie-lands of Nebraska, far from any mines, and not even within sight of any mountain that could suggest either geologic disturbance or prospective digging. Like many others he entered mining through the door of surveying, in his case it was railroad work. He followed the rails into a mining district and shortly afterward was given an opportunity to survey the workings of a mine, in Utah. That marked the beginning of his career as a mining engineer; he did not graduate from a school of mines nor undergo any special academic preparation; he became a mining engineer by doing the work of a mining engineer, which, unquestionably, is one of the most

effective methods of qualifying for the profession. He is one of those useful men who, starting with nothing more than high-school instruction, have made the most of the greater school of experience, aided by persistence and native intelligence, plus character. He became proficient technically by dint of study during spare time; to technical science he added an understanding of his fellow-men—an essential knowledge. The leasing of a small mine on his own account was an experience that must have helped greatly in equipping him as an adviser to others. It was a personal venture—an adventure—and it gave him, we surmise, a first realization of the economics of mining and a keen appreciation of the fact that the basic purpose of mining is to make money, not to furnish jobs for excellent young men. The appointment to the superintendency of the Bunker Hill was an important event in his life, because it enabled him to prove his metal and enlarge his acquaintance among men of importance in Western mining. Mr. F. W. Bradley tells us how he came to know Mr. Burch through an experience that they shared while traveling in Oregon. They were overtaken by a snowstorm so violent that two of their horses succumbed, but eventually they reached the shelter of the cabin for which they were making, because Mr. Burch broke trail with indomitable courage. He showed similar courage and persistence while in charge at Kellogg; he used to go through the workings of the Bunker Hill twice a day. A capacity for hard work and long hours has stood him in good stead ever since. Fortunately he has been blessed with a fine physique, rendering him capable of great exertions. Mr. Oscar Hershey, his partner, tells us how as geologist to the Bunker Hill company he was called upon to take Mr. Burch into the field and show him the evidences of faulting. He led Mr. Burch first as rapidly as possible to the top of the highest peak in the district, and thereby ascertained that his associate's reputation for endurance was justified. In Colorado, one may notice the great number of wagon-roads leading to insignificant prospects, the cut made for the road in several instances being deeper than the shaft. A mine-owner is said to have been asked to explain the anomaly. "Well", he replied, "you know here in Colorado we can't get an engineer to visit our mines unless we haul him up in a buggy." That may be apocryphal; evidently it is archaic; but in any event it does not apply to Mr. Burch. He would go on foot or on snowshoes, in a submarine or an aeroplane, if necessary, to reach his objective. He is extremely active in his profession. When we meet him at intervals, on train or ferry, on his way to and from his office, we learn usually that he returned to town yesterday and is leaving tomorrow or the day after. He seems rarely to 'take five', or 'taper off', as the Cousin Jack says. Capacity for hard work will go far, but it is not enough. Our friend has powers of keen observation, quick thinking, and good judgment. An excellent engineering equipment, the reader will say. Besides these he has a good temper; he is not easily ruffled and is kind to those with whom he comes in contact. Another of his associates says that the only time he saw Mr.

Burch lose his temper was at the close of a long hard trip over a muddy road in central Idaho. The driver persisted in whipping the horses, although it was manifest that they were doing their best. Finally they stalled. The driver proceeded to use his tongue and his whip with equal violence. Mr. Burch expressed his opinion scorchingly, and later ordered the staff at the mine to give the driver no more business. A decent consideration for mankind is shown in his replies to our queries dealing with the labor problem and welfare work. At Kellogg, Goldfield, and Plymouth he did much to establish pleasant relations between the company's representatives, the employees, and the people of the town. That is good management; without good-will all round it is impossible to ensure efficient work; the disagreements that cause so much loss of time and money are like the screw-driver thrown by a vicious man into a delicate mechanism. Mr. Burch succeeded in his welfare work, as it is now called, because he was sincere in his purpose. Many similar attempts by company officials, presidents, managers, or superintendents have failed because they lacked the genuine humane interest in the workers without which welfare work is a Dead Sea apple, or, to use the vernacular, proves a lemon. The 'open shop' is a question that tests intellectual honesty, for most employers and managers do not face its implications fairly. If capital is organized, it is well that labor should be organized also, in order to facilitate collective bargaining. The 'walking delegate', of course, prostitutes a workable arrangement to his own selfish purpose, using his agency to promote trouble rather than to smooth difficulties. Mr. Burch talks good sense on this matter. He has a characteristic that is the mark of the truly scientific mind, he is intellectually honest; he does not 'kid' himself, as many well-meaning people do. Thus he is quite frank in deprecating the present method of obtaining evidence in apex suits; he suggests special courts for such litigation. We commend what he says to our readers. He is equally frank about the war-minerals business, which has left so many heartburnings in its wake. He has no doubt in regard to the disingenuous effort of the gentlemen at Washington to restrict claims for compensation to those who were solicited personally by Government officials, ignoring the larger number that were reached by official propaganda in the press. Twice in the course of the interview, Mr. Burch turned the tables on his interrogator, by asking questions himself. That made the performance more natural, for every man likes to retaliate after a while. The interview should appeal to the young men of the West, for it tells how one of them 'made good' and achieved success. Mr. Burch has definite ideas concerning the kind of young man that ought to go into mining as a profession. He specifies the qualifications, but, naturally, he does not stress the special ones that helped him to succeed. One can learn to work hard, to observe accurately, even to think honestly, but the force of character that opens the ways of the world to a true man is not acquired at school or at college. "Which of you by taking thought can add one cubit unto his stature?"

DISCUSSION

Mr. Sulman and the Medal

The Editor:

Sir—You have referred in recent issues of your journal to Mr. H. L. Sulman's paper published by this Institution in November last and also to the award of the Gold Medal of the Institution to Mr. Sulman. As you appear still to be under some misapprehension as to the terms of the award of the Medal, I am directed by my Council to again inform you that it was awarded to Mr. Sulman "in recognition of his contributions to Metallurgical Science with special reference to his work in the development of Flotation and its application to the recovery of minerals".

The Gold Medal of the Institution is awarded for conspicuous services of a life-long character in the advancement of the science and practice of mining and metallurgy and it is not and has never been awarded for any specific paper as you will see on reference to the list of distinguished recipients in the past, amongst whom are the late Dr. James Douglas, the late Dr. R. W. Raymond, and the late Mr. Hennen Jennings.

C. McDERMID.

London, July 22.

Secretary of the Institution of
Mining and Metallurgy.

[We refer to this letter on another page.—EDITOR.]

Mining Near Joplin

The Editor:

Sir—My attention has been called to a news paragraph in your issue of July 17, in which it was stated that "many mining companies, including practically all of the larger producers of zinc and lead in the Tri-State district which centres around Joplin, have agreed upon a plan of curtailment that is expected to force the price of ore to \$60 per ton". It would seem from the above that the mine-operators in this district had gone together to restrict output for the sole purpose of increasing the price of their products.

The facts of the situation are that for many months the shortage of freight-cars has caused an accumulation of ore in the bins of the mine-operators. At the present time there is a total of 64,000 tons of zinc concentrate stored in the bins of the district. Every summer the operators are faced with a shortage of labor, due to the requirements for men in the Kansas wheat-fields. This year the crop was unusually large, and it was certain that many of our men would be absent for a profitable vacation, leaving us short-handed. It was therefore decided by the operators to shut-down for a two weeks

period, in order to give our men this vacation, and also if possible to permit the shipment of the large accumulation of ore [meaning 'concentrate', probably.—EDITOR] in the bins.

The public at large has not realized that this district has for many months suffered severely from a shortage of freight-cars, and our advices lead us to think there is not much hope for improvement in the immediate future. We cannot continue indefinitely to produce more than we are able to ship, and it has therefore been mandatory for us to adjust our production to our shipping facilities. I would appreciate it if you would correct the wrong impression contained in your issue of July 17, and I assure you that this courtesy will be much appreciated by all of the operators in this district.

EDGAR Z. WALLOWER, Governor,

Tri-State Chapter of American Mining Congress.

Joplin, July 26.

More Books Written in a Hurry

The Editor:

Sir—In the 'Press' of July 10 I discussed what Vernon Kellogg said about Herbert Hoover's work at Broken Hill, Australia; this time I would like briefly to quote a few passages from 'The Making of Herbert Hoover', a biography by Rose Wilder Lane and Charles K. Field in the 'Sunset' magazine for July.

"The big firm of Bewick, Moreing & Co. in London had asked Janin [Louis] to recommend a young American mining man to send to Australia; salary, one thousand pounds a year. Did Mr. Hoover want the job? . . . They write that they have to have a man not more than thirty years old, with seventy-five years experience. A man over thirty can't stand Australian climate and living conditions, they say, and it takes a man of seventy-five to handle their problems down there. . . . He thought it over. . . . It was a great opportunity if he could make good. . . . It was settled. . . . He was to leave at once for Australia, by way of London. . . . By midsummer he was buried in work, with plenty to do and precious little time to do it in, it seemed. He had charge of the Coolgardie office of the company [Kalgoorlie is meant, as B., M. & Co. had no office at Coolgardie], the most important office in the colonies. . . . Things were getting in splendid shape. . . . Encouraging compliments were coming constantly from London. Simply the introduction of a little hard work and a lot of American sense. Mining there was in the kindergarten stage of sixty years ago in California. It fairly made an

American engineer weep. Already his introduction of American methods was increasing the output of the mines and threatening trouble with the workmen. He found that the miners were using the old 'double-jack'—one man holding the drill while another struck it with the sledge. It was one of the innumerable small details that he described as sickening. The single-jack was introduced into the mines and he faced a rebellion of the miners. They refused to use the new tools; they flung them into the machinery of the stamp-mills; they were found in shafts and tunnels doggedly working in the old way. . . ."

! !! !!! ? ?? ???

Why discuss such rubbish? and there is more of it too. Shades of eminent Australian mining men rise and smite these biographers, or whatever the writers consider themselves. And shame on the 'Sunset' magazine for widening the distance between America and Australia, instead of making it less, by deprecating Australian efforts, which have given so much to the mining industry.

[Editorial comment will be found elsewhere.—EDITOR.]

The Status of Gold

The Editor:

Sir—The position of the gold-producers today suggests to my mind that there is something fundamentally wrong that they should consider.

Briefly: Under the gold standard, gold establishes the basis for money credit, but the producers of gold do not get the credit. The producer turns in his gold for about \$20 per ounce; that same ounce of gold has a money credit which the banking interests get.

The gold-producers, in my opinion, can correct this situation and come into their own only by forming a 'Gold-Producers Bank', where all production will be deposited. The banking or industrial interests can then obtain the gold by payment of the credit-value for gold, or it may be possible for the Government to issue currency to such a 'Gold-Producers Bank' upon the credit system in operation.

In any event the gold-producers would get what belongs to them rightfully, and the credit they establish would be in their control.

I am advised that there is no law compelling gold-producers to sell their production to the Government.

Reno, Nevada, August 7. F. A. WRIGHT.

Concerning Silver

The Editor:

Sir—Recent communications from Mr. Butters have attracted my attention, and I think a little further publicity is desirable.

It is significant that Mr. Butters seems to agree with the Treasury Department that "silver is cheaper now than it will be in the future". He has suggested something of real benefit to the silver miner, "that the Mint

should be willing to exchange silver coin for the bars which the producer deposits". I venture to say that legislation to this effect would be of greater benefit to the whole mining community than the proposed "bonus on gold", as it would stimulate the mining of mixed ores, which have gold only as the metal of relatively lesser value. Our depleted gold reserve would certainly be largely increased if base metals and silver were mined more extensively.

While Mr. Butters does not stand sponsor for bi-metalism, he advocates something which in effect would be of equal value to the silver producer. As a side-light on this phase of the question I would refer to what Mr. Govett said in his speech on the gold problem. "The Indian government embraced the bi-metallic heresy with fine contempt for the economic law that 'it is not possible to fix a ratio between two fluctuating values.' . . . Curiously enough, though entirely unsound, it was good business. For many years it looked as if they were right." This raises the point that it would be "good business" for the United States to take a lesson from the Far East where is our biggest market for silver.

As a query, and for the purpose of provoking further discussion, I would like to ask mine-operators who are producing both gold and silver to consider seriously Mr. Butters suggestion.

FRANK L. SIZER.

San Francisco, August 18.

The Oil-Shale Industry

The Editor:

Sir—I note in your number of August 7, an article by Martin J. Gavin on 'Oil-Shales and Their Economic Importance'. It appears to me that Mr. Gavin has pretty thoroughly damned the enterprise with faint praise. I am interested to note that in his remedies for the coming oil shortage in this country, Mr. Gavin suggests, among others, importing oil from the "enormous potential supplies of Mexico", and the "gradual change in the design of our present internal-combustion motors, enabling them to use lower-grade fuels".

I understand from rather well informed sources that the "enormous potential supplies of Mexico" are not as enormous or as potential as they are cracked up to be; that in fact the territory favorable to drilling so far discovered is very restricted, and that many of the big producers are suddenly going salt. I am also anxious to know where Mr. Gavin is going to obtain his supplies of low-grade fuel even if our present internal-combustion motors are gradually changed for its use. Kerosene and distillate are rapidly becoming matters of history, gas-oil is selling at a high premium in the Middle West, and fuel-oil is crowding gasoline as far as a shortage is concerned.

Continual harping on these two "solutions" grows wearisome. If we have a situation to face, let us at least face it frankly.

DAVID E. DAY.

San Francisco, August 10.

EUREKA, UTAH

Albert Burch: A Western Engineer

An Interview, by T. A. RICKARD

You were born in the West, Mr. Burch?

I was born at Peru, Nebraska, on January 8, 1867.

What was your father's occupation?

Methodist minister.

How did you get your taste for mining?

Through surveying underground. There was no mining in our part of the country. The first mine I saw was the Homestake, in South Dakota, when I was a boy on a railroad survey in 1882.

What was your education?

The equivalent of a high-school training at the State Normal School of Nebraska, followed by one year, when I was 16, in York College in the town of York, also in Nebraska.

What was your first job?

As a boy I worked during the summer on gardens and farms for a few cents per day. My first important job was with the Burlington railroad, in 1880, when on Friday afternoons and Saturdays I made computations on earthwork quantities. The next summer I commenced work for the same people in the field, beginning as back flagman and advancing to chief of a locating party. I remained with them until 1888, when the locomotive engineers strike caused them to cease construction of new lines.

How long were you engaged in railroad work?

Until May 1889.

What led you to your first engagement in mining?

While I was in charge of construction of a branch railroad to the mining camp of Eureka, in the Tintic district, Utah, I was asked by Hank Smith, who was at that time superintendent of the Bullion Beck & Champion mine, to do their underground surveying and make myself generally useful as an outside foreman when there was not enough to keep me busy with the surveying. I stayed there until the latter part of 1891.

What pay did you get?

I got \$180 per month, with my room and board. In the middle of 1890 I gave up all the work at the mine except the surveying and the construction of a water-works system, and took a commission as U. S. Deputy Mineral Surveyor, which proved more profitable. I was married on January 1, 1891, and within a few months it became evident that my wife could not stand the altitude, so I resigned from the Bullion Beck & Champion, and moved to Salt Lake, where I opened an office as Mineral Surveyor late in 1891, but I continued to make periodical trips to the mine for the purpose of keeping up their surveys. On the first day of January 1893, I was offered the superintendency of the mine and remained in charge

until about April 1894, when the property changed hands and I was fired.

What was the reason?

The mine passed into the control of others. There had been a bitter fight for the control of the mine and I was believed to be a partisan of those who had formerly controlled it.

Did you return to Salt Lake?

Yes, and re-opened my office there as Deputy Mineral Surveyor. I also took a lease on the Northern Spy mine, in the Tintic district, which I operated under a lease for a year. This proved to be about the first easy money I ever made. During that year I became interested in the local geology and conceived the idea that a block of ground lying between the old Mammoth mine and the Centennial Eureka ought to contain a considerable quantity of ore. I interested C. E. Loose in the matter of developing it and secured options on the property. Loose carried the enterprise alone for about six months and then incorporated the Grand Central Mining Co. The Grand Central was financed by Loose, the present Senator Smoot, an Ogden lawyer named David Evans, and a hotel proprietor of Provo named Lafayette Holbrook.

How did it pan out?

It proved successful, though nearly all of the original money subscribed, \$125,000, was expended before any ore was found. It finally became a profitable mine and it has paid about \$1,500,000 in dividends and is still paying dividends. It suffered greatly on account of apex litigation with the Mammoth.

So you had your first taste of apex litigation, Mr. Burch?

I was personally touched by it because the shares which I had valued at \$9 declined within a year to about \$4, at which price I sold my holdings in the Grand Central, after removing to Wardner, Idaho.

When did you go to Wardner?

In the spring of 1897, but before going there I acted for a few months as substitute manager of a little gold mine in the western part of Oregon. It was owned by an English company—Lawler's Gold Mines, Ltd.—and Mr. Lawler was the manager. He went to Europe in the fall of 1896 for treatment of his eyes and I took his place during his absence. It was while I was manager of this little concern that I first met F. W. Bradley, in February 1897. He came to make an examination of the Lawler mine for some of the shareholders whom he had just met in London. At the conclusion of the examination, he suggested that in case I should want to leave the Lawler mine, he would be in position to offer me the superintendency of the Bunker Hill & Sullivan. He evidently knew that when his report reached London the Lawler mine would no longer be operated and in the course of two or three months this developed. I went to Wardner as superintendent of the Bunker Hill & Sullivan on the first of May, 1897.

Then, you were in charge of the mine at the time of the destruction of the mill at Kellogg?

Yes, I was; and saw the mill blown up.

Looking back, what is your opinion as to the merits of the industrial quarrel in the Coeur d'Alene at that time?

I think that the wages which were being paid by the Bunker Hill & Sullivan just prior to the strike were perhaps too low considering the era of general prosperity that was then beginning. However, before the mill was blown up, the wages of all the Bunker Hill miners were advanced to the figure asked by the Union; but the Bunker Hill company had only a few Union men in its employ. As the total number of employees was 550, and only 90 went out on strike, that represented probably more than the full strength of the Union in the mine, because some men were undoubtedly intimidated. The fight really was for Union control of the district. The Union had been successful in obtaining control of all other mines except the Bunker Hill and had determined to make an example of it. The mill was not blown up by the Bunker Hill employees but by others who came from the outside. I still approve the stand taken by the Bunker Hill management as far back as 1892 against the Western Federation of Miners, who then controlled the Union. I approve their stand for an open shop, which they have continued from that date to this. There was no resistance made by the Bunker Hill officials or employees because the entire county government was in the hands of the Western Federation and resistance of any sort would have meant bloodshed, and prompt prosecution of the resisters rather than the attackers.

You must have your opinion in regard to the bull-pen and other repressive measures that were taken later by the mine-owners assisted by the United States troops.

The action of the State government in rounding up and confining a large percentage of the male population of the county was, perhaps, drastic; but so far as I was able to observe they were well treated, except for confinement. They were detained in buildings constituting what was called a bull-pen because there was not sufficient jail capacity in the county to contain the number under arrest. Most of them were held only during the necessary examination of witnesses before the coroner's jury, which had to determine, if possible, who was responsible for the deaths of three men who were killed. The evidence gained at the inquest was used to a considerable extent later in the trials of those who were indicted, but comparatively few of those who were really guilty were ever brought to trial. On the other hand, a great many who were innocent of any real intent to commit a crime were forced by their officers and the radical element in the Union to join in the attack upon the Bunker Hill property and to the extent that they were innocent participants in that attack they probably had a real grievance against the officers who arrested them and confined them for one week to three or four months in the bull-pen. The point is this, probably two-thirds and perhaps even three-fourths of the members of the local union of

the Western Federation of Miners were opposed to violence, but they were in much the same position as poor dog Tray, who got into bad company, and the officers of the law did not discriminate between those who were willing and those who were unwilling to commit crime.

How long did you remain as superintendent of the Bunker Hill?

Until June 1901, when I was promoted to manager, remaining in that position until January 1, 1903, although I was nominally manager until 1905. Later in 1908 I was appointed consulting engineer to the company with a view especially to the conduct of a litigation in progress with the Federal Mining & Smelting Co. From April 1903 until January 1905 I was a member of the firm of Burbidge & Burch, with offices in Spokane, and engaged in the development of various mining properties under option. My partner was Frederick Burbidge, now living at Wallace, Idaho.

Were you successful in developing anything of importance?

No; so in January 1905 I left Spokane and opened an office in San Francisco, where I have remained up to the present time in practice as consulting engineer.

You were connected personally with the Plymouth Consolidated, were you not?

The properties now owned by the Plymouth Consolidated Gold Mines, Limited, were largely held by the estates of Alvinza Hayward, Walter S. Hobart, and by Charles D. Lane. For some time I had been consulting engineer to the Chicago Exploration Co., headed by J. D. Hubbard. On one of his visits to San Francisco, Mr. Hubbard met Gordon Hall, who was attorney for C. D. Lane, and Mr. Hall talked with Mr. Hubbard about the Plymouth property and persuaded him to ask me to look it over. I did so, and obtained options upon the property owned by the Hayward and Hobart estates, and Lane, and also upon several adjoining properties which I thought should be included. This took three or four months; in the meantime the revolution in Mexico commenced, with the results that the Chicago Exploration Co., which was largely interested down there, decided not to take up new enterprises. This left the Plymouth option on my hands. I tried to interest various parties during the summer of 1911, but was not successful until I met W. J. Loring of Bewick, Moreing & Co. He came to the United States on a visit to his mother. Through his firm, British capital was interested in the development of the Plymouth by means of a corporation called the California Exploration Co. The development period extended from late in 1911 until early in 1914, when the Plymouth Consolidated Gold Mines, Limited, was organized, the control of the shares being taken by the California Exploration Co., the remaining shares going to Mrs. Lane, Mr. Hall, and myself. Since then the mine has been operated continuously and has practically returned its entire cost, namely, \$1,000,000, and still has good prospects.

While you were consulting engineer of the Plymouth, you built a club-house at the mine and did other things to

promote loyalty among the men. What are your views on welfare work?

Under the head of what is called 'welfare-work' a great many things are done that do not really help to promote good feeling between the management and its employees, because there is frequently a lack of genuine sincerity in the conduct of the work. My own belief is that welfare-work, so-called, is only useful when the head of an enterprise takes a genuine interest in his employees. A man, or a crowd of men, will quickly detect the lack of sin-

MR. BURCH AS SURVEYOR AT EUREKA IN 1891

cerity, if it is lacking; and that affects anything that can be done to promote cordial relations. Human sympathy must exist between the management and the men, for without it no amount of money expended for club-houses, entertainments, housing, and sanitation can be of real value in promoting cordial relations. It becomes an empty shell without the kernel of genuine feeling.

With what companies have you been connected in later years?

In 1911 I was consulting engineer to the Goldfield Consolidated Mines Co., at Goldfield, Nevada, and during the years 1913-1914 I was general manager for the same company.

You must have had experience with ore-stealing, and taken measures to prevent it?

No, I did not. That was before my time. We had difficulty in finding ore rich enough to return a profit after it was handled in the mill, rather than through a custom assay-office.

What would you regard as the most pleasant feature of your management of this mine?

Aiding in the building up of a more cordial feeling between the business-men and townspeople of Goldfield and the management of the mine. It commenced with a dinner to which about 250 people of the town and the more important mine employees were invited. On this occasion a club for better social intercourse between all classes of the community was launched. It aided greatly in establishing more cordial relations between the people of the town and the company. There had been a spirit of suspicion between them, although there was really no reason for it. This reminds me that long before, when I was at Wardner after the strike of 1899, a local union was organized largely on the initiative of Mr. Bradley, and it served as a pattern which I was able to follow in later years at Goldfield and Plymouth. There is no question but that a man's success in life depends largely upon his standing in the community in which he lives and in which he does business, and the same applies to a corporation. Unless the corporation has the good-will of the people in the local community, it will always be subjected to all kinds of annoying and frequently expensive impositions. Whenever there is a spirit of distrust, you have a condition of constant bickering and attempts at gouging, all of which cost real money to the corporation; therefore, either from a standpoint of comfort in living or in actual profits, the corporation can well afford to spend some thought and some money upon maintaining cordial relations between itself and the people in the community in which it operates. It is largely the spirit of the people of Kellogg and Wardner that has maintained industrial peace at the Bunker Hill mine for the last twenty years.

Why did you leave Goldfield?

I was tempted and fell. Mr. Jackling persuaded me to go to Butte in the interests of the Butte & Superior Co., in connection with its litigation with the Elm Orlu. This made it impossible for me to continue my duties at Goldfield.

When did you become consulting engineer for the Mountain Copper Co.?

In 1913. Our firm of Burch, Caetani & Hershey became consulting engineers to the Mountain Copper Co. in 1913. Gelasio Caetani was in London early in 1913 and met yourself and through your introduction to then Captain, now Major, Lawson, who was the chairman of the board of directors of the Mountain Copper Co., a connection was established with them in that year. Mr. Caetani, as you know, is an Italian mining engineer, who has specialized in concentration. For instance, he re-designed the Bunker Hill & Sullivan concentrator at Kellogg, Idaho, and designed the mill of the Mountain Copper Co. at Keswick, re-constructed the mill for the

Tomboy Gold Mining Co. in Colorado, designed a plant and mill for the Plymouth Consolidated of California, and has acted in a consulting capacity for many concerns interested in the concentration of ores. At the beginning of the World War he returned to Italy and became an officer of engineers in the Italian army. He little expected at that time that he would remain in Italy, but owing to the death of his father and other changes which were brought about by the long-continued war, he finally decided not to return to the United States. Thereby a very valuable man is lost to the profession of mining engineering. The firm of Burch, Caetani & Hershey was organized on the first of January 1912. The third member of the firm being O. H. Hershey, the well-known geologist for the Bunker Hill & Sullivan and other concerns. Since the decision of Mr. Caetani not to return, his place in the firm has been taken by Lloyd C. White.

Looking back, Mr. Burch, over your thirty years of experience, what are the chief changes in mining operations and in the men by whom they are performed?

The introduction of much lighter and more readily adaptable machine-drills is probably the thing that has aided most in bringing down the cost of actual mining operations and also contributed largely to the comfort of the men themselves. The development of electric power and its transmission to all parts of mine-workings has also aided greatly in reduction of cost and in addition to comfort. A study of ventilation in many mines has aided materially. So far as the miners themselves are concerned, I look back to those whom I knew first as a sturdy race of Cornishmen and Irishmen. They have practically disappeared from the larger mining districts, though they and their children, and grandchildren, are found in some of the smaller and older districts of the country, such, for instance, as Grass Valley in California and Central City in Colorado. The miners who succeeded them in the regions with which I was familiar were largely Swedes and Finns. There are still a great many Finns employed in sections of the country, but very few Swedes. Most of the miners now are from south-eastern Europe, and, in my opinion, do not measure up to the standard and type of men that I knew at the mines in my younger days.

To what extent are steps being taken to promote Americanization, and to what extent do you think such steps can be taken successfully?

I am not familiar with the work which is being done by the various Americanization organizations, nor am I in close touch at present with any large operations where individual companies are attempting to carry on a campaign of Americanization. I have no doubt that systematic work of this kind will attain favorable results if sufficiently persistent. I believe that the more we can educate and imbue the foreign element with American ideas and American ways the better it will be for the future of mining, as well as for the country. I also believe that the training of native-born Americans in mining is one of the things that will have to be done in the next few years.

THE PLYMOUTH STAMP-MILL IN AMADOR COUNTY, CALIFORNIA

Have you done anything in the way of night-schools?

I have not. I tried to get some companies interested in private night-school training for the younger employees of the mines. The idea did not meet with a favorable reception, and nothing was accomplished.

You have participated in a good many mining litigations?

Not very many. About half a dozen, but they all happened to be important cases.

May I ask you whether you have any opinion as to the present method of eliciting facts before the Court, and whether you can suggest any better method?

I certainly think that the present method is wrong, because it develops partisanship upon the part of the men who should be studying questions from a strictly scientific standpoint and because of the great waste of money which the method entails upon the litigants. It is a waste of energy and a waste of money and might be avoided by the development of special courts for trying of mining suits. This is not an original suggestion. It is one that I obtained from Judge Farrington of the U. S. District Court of Nevada after the long drawn-out trial of an extra-lateral suit in the court in 1912. He expressed the thought well when he said: "Here I have listened for three months to eminent scientists taking absolutely opposing views upon scientific questions and I as a judge not trained in geology am called upon to decide which group is right." He added: "This is a farce and it could be cured by the establishment of specially trained courts for the disposal of such litigation."

Therefore, you would not approve the retention of present courts with provision that the expert witnesses be engaged by the Court itself?

No, for the obvious reason that the Court would still be left very much in the dark as to the facts because of lack of training upon its part in matters of geology. I do not know whether it would be possible under our system of government to require that cases of this kind be submitted to Boards of Arbitration instead of the present courts, but if this can be done, I would suggest a Board of Arbitration consisting of, say, one lawyer, who had

been accustomed to mining practice, one mining geologist, and one mining engineer, and allow the arbitrators to examine the premises and arrive at their own conclusions as to facts.

Thereby rendering it unnecessary to have an array of expensive witnesses?

Yes, that would be the result, and it would also frequently result, I think, in obtaining just decisions or compromises.

You were engaged in stimulating the production of minerals during the War, for the Government, were you not?

I regret to say that I was. I thought it was my patriotic duty to do what I could toward advancing the interests of the nation in connection with the War and did not feel that I could probably be of much service in the Army, and therefore did not attempt to enter the Army, but early in the War made application to Government bureaus for employment in a volunteer capacity. I was accepted as a consulting engineer for the Bureau of Mines and was first sent to Cuba to investigate the manganese and chrome resources of that island. Later, I was placed in charge of the district embracing Oregon, California, and other Western States, with a selected field force for the purpose of examining and reporting upon chrome mines in the territory and advising the operators of the mines to the end that production might be made as rapid as possible. This work occupied practically all my time from the beginning of May, 1918, until after the signing of the Armistice. It then became evident that the industry had been over-stimulated. I have deep sympathy for those who were urged by the various government agencies to begin the production of war minerals as a patriotic duty; but have no sympathy for those who have used this as a cloak to cover exorbitant demands for the reimbursement of funds that were never lost at all.

Do you consider that the decision of the Secretary of the Interior, acting on the advice of the Attorney General, that only the personal solicitations of the Government bureaus should count as proof of work

done in response to the Government was unfair? Do you not think, with me, that the relief given should include all those who responded to the request of the Government as advertised in the press, daily and technical, of the day?

Certainly I agree with you, because a direct personal request was made of comparatively few people and usually the larger and more important operators. The small producer was not approached directly, and yet frequently it is the small producer who has to stand the largest percentage of loss.

How do you regard the question of unionization of mine labor? In other words, is it feasible or practicable to maintain the open shop?

I am a strong believer in the local union, which affords machinery for collective bargaining, the handling of grievances, and a closer approach between the management and its employees without the danger of sympathetic strikes, which are brought on through causes in which the local people can have no interest or knowledge whatever. I do not believe in the salaried business agent, or 'walking delegate', as he was formerly called, who feels that he must stir up trouble and cause turmoil in order to hold his job. I think perhaps if his relationship to the union would change to something like that of the Chinese doctor who is paid a regular fee as long as he keeps his patient well and none while the patient is sick, it might make a great difference in the handling of labor questions between the business agent of the union and the manager of the property.

And you undoubtedly wish the manager of the mine likewise to play the part of the Chinese doctor?

He does now, for he is paid his salary as long as he makes good; when he cannot, he loses his job.

To what extent do you approve of the more modern practice of employing graduates as shift-bosses in mines?

My experience in that has been a little unfortunate. I have employed college graduates as shift-bosses in mines with rather poor success unless the college graduate before, as well as after, entering upon his college career had had a considerable mining practice.

You mean as a working miner?

Yes. The graduate of a mining school who comes from a mining district, was born and reared in a mining district, can usually be depended upon to make a good shift-boss if he has the other necessary qualifications, including physique, but the graduate of a mining school, who is reared in the city, or even in the country districts, where he did not absorb the mining atmosphere, does not as a rule make a good mining man in comparatively subordinate positions. What do you think about it?

Well, Mr. Burch, I think this, that comparatively few young men have the physique as well as the intelligence to do the hard work of the miner preparatory to becoming shift-bosses, and I believe thoroughly that the sort of leader of men that the shift-boss must be is only developed by actual experience in

the manual labor that his men are performing. Would you have made a good shift-boss?

I would not, because I had not the practical experience that goes with the duties of a shift-boss, or that leads up to a knowledge of the duties of a shift-boss.

Whereas your experience in surveying and in railroad work did prepare you to become the superintendent of a mine?

It helped.

You have taken a keen interest in the California Metal Producers Association?

Yes, after observing for two years the operation of the Nevada Mine Operators Association, which I assisted to organize, I thought I saw the need for something along similar lines in California. Therefore in 1914 I invited some eight or ten prominent mine operators in California to lunch with me at the Engineers Club, San Francisco, where, after a few hours discussion we commenced the organization of the California Metal Producers Association. This, I believe, has been of value to the mine operators in California. It is now affiliated with the American Mining Congress and embraces within its membership nearly all the large mines and many of the small ones in the State.

What work does it do more particularly?

The first and most important work that it did was to bring about a spirit of harmony between the mine operators and the newly organized California Industrial Accident Commission; it aided in formulating the rules that were promulgated by that Commission in connection with the operation of mines; it supported the Commission in its efforts to reduce rates for workmen's compensation insurance, thereby saving to the operators considerable sums of money. It has maintained an inspection service for the mines of the State for the last three or four years, the Inspector of the Association having at all times harmonious relations with the inspectors of the California Industrial Accident Commission, and in legislative matters it has been of considerable aid to the mining industry in combating vicious measures. These are among the principal things accomplished by the Association, though a great deal of attention has been given to First Aid work and the general improvement of operating conditions about the mines.

You and I, Mr. Burch, had a talk two years ago about the American Mining Congress, and we agreed that it was deserving of support as an agency to represent the mining industry at Washington, and to do for the national industry what your California Metal Producers Association was doing in California. I would like to have your opinion as to the recent extension of the activities of the American Mining Congress in establishing bureaus for statistics and technical information on a somewhat grandiose scale.

I believe that, being in close touch with the various Government bureaus in Washington, it has a field of use-

fulness along the lines suggested, in the matter of collecting and disseminating information, not to the public nor to the mining public, but to members of Congress, who are sadly in need of correct information regarding the various measures that come up before that body. The field, you might perhaps consider, is fully occupied by the American Institute of Mining Engineers, scientific and technical publications, the Bureau of Mines, and the Geological Survey; but in my opinion there is still a good field for the activities of the American Mining Congress along the lines stated. It is a fact that can be seen by any one who goes to attend committee hearings in Congress that little attention comparatively is paid to the statements made by the Bureau chiefs and Bureau employees as against statements made by rank outsiders, and since the American Mining Congress makes a specialty of looking after national legislation as it may affect the mining industry, it has to maintain a position

can be kept within bounds it may be worthy of support. What do you think members of Congress really want for their consideration of matters coming before them?

They really want accurate information on various subjects coming from people in whom they have confidence.

Does that mean that they have no confidence in the Bureau of Mines and the Geological Survey?

The experience to be had in the hearings in connection with the War Minerals Control Bill indicates clearly that Congressmen pay but little attention to statements of such eminent men as Van. H. Manning and George Otis Smith as compared with outsiders. The attitude of the average Congressman is that the men in the Government bureaus are trying to get something for the bureaus, whether it is needed for the country or not, and he looks with suspicion on measures which are advocated by these

THE MINNESOTA CONCENTRATOR OF THE MOUNTAIN COPPER CO.

ensuring its officers a respectful hearing. I may mention here that this has been accomplished largely by the efforts of James F. Callbreath. I believe that, if not carried too far, the expansion which has been commenced will be of added benefit. Mr. Callbreath has had to depend in the past largely upon his own ability to collect facts without much assistance and having now the beginning of a corps of assistants he can save his time for more important work. What do you think about it?

I think you have stated the case correctly in the last sentence where you refer to the "more important work". It is a matter of relativity as to whether lobbying—using the word in a kindly sense—and the watching of legislation is not more important than the establishment of further statistical bureaus; but, of course, it may be said that the one cannot be done without the other; that is to say, the stirring of legislation is impossible without an adequate source of data such as the organization can collect for the purpose, so you and I will agree that some of this expansion is warranted and that if it

bureaus. Whether this attitude be right or wrong, that is the attitude of the average Congressman.

Would you advise a young man today to become a mining engineer?

If the young man has the physique necessary to stand a great deal of hardship in all kinds of climate, and also has some of the elements of a diplomat in his make-up, in addition to the technical knowledge which he will gain by taking a mining course, Yes; otherwise, I would say No. There is going to be a continued demand for mining engineers and continued call for young men in minor capacities about the mines and mills. There are a great many more little places, or little positions, than there are big ones; too many of the men who enter upon the profession of a mining engineer get into ruts early in their careers and never seem to be able to extricate themselves. Just why this is, is hard to determine, but sometimes it is because of the difference in ability in different human beings; frequently it is a question of luck, and oftentimes it is due to the lack of diplomacy.

The Knee Lake District in Northern Manitoba

An Official Report

The development of mining in Manitoba has led to some renewed interest in the upper Hayes River basin. Early geologic exploration proved the existence of an area of rocks similar to those associated with the gold and copper ores of the district north of the Saskatchewan river, and a few prospectors paid hurried visits to Oxford and Knee lakes. One party, directed by H. M. Paull of the Pas, staked a number of claims on the north shore of Knee lake and did a considerable amount of development work on them.

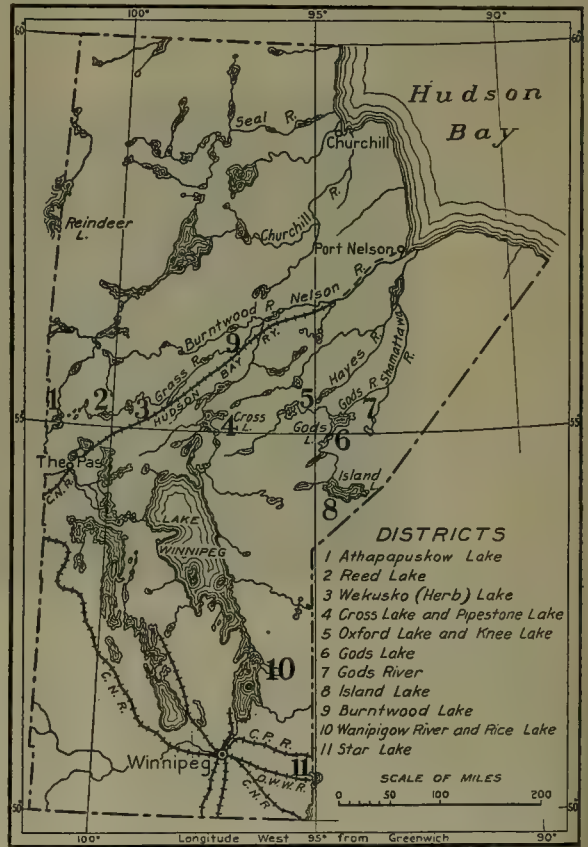

The Knee Lake district, in common with other parts of the pre-Cambrian region in Manitoba, is characterized by low relief. In some places the surface is hummocky and rugged, but much of the district is so deeply covered by clay and sand that the solid rocks are not exposed and the inequalities of the solid surface are almost completely smoothed out. Along the shore of the lake, ridges of rock are exposed rising 10 to 30 ft. above the water. Inland the rocks are covered by fine sand and clay and by muskeg, although the elevation may gradually increase up to the divide between the river systems. Thus from points four or five miles from the lake the country appears as a plain sloping gently down to the hollow in which the lake lies. The hollow, however, is considerably deeper than the lake at most places. Hence the solid rocks appear beneath the plan as rugged ridges bordering the lake shore.

The country at the south end of Knee lake is the most rugged part of the region. It is underlain by heterogeneous rocks, the resistant bands of which stand up above the more easily eroded formation. Even in this locality the rock exposures do not extend far inland from the waterways. At the lower end of the lake the country is flat. Outcrops are rare even along the shore, and beaches of sand and boulders extend for long distances, forming a natural levee behind which lie swamps and muskegs.

Hayes river is the only large river in the area examined; very few tributaries large enough for canoe travel join it in the Knee Lake district. A small creek enters the north end of Black lake. It is used as a canoe-route leading to Deer river, which empties into the Hayes a considerable distance below Knee lake. Muskegosip creek drains a lake two miles long into the west end of Knee lake. Wolf river drains Swampy Portage lake and Pisging Eagle lake into the large bay south of Magnetite narrows. Though the volume of water carried by Hayes river is not great, it is the canoe and York boat route to Gods and Island lakes. Below Magnetite narrows, Cinder creek empties into the extreme western bay of the lake. It is the outlet of Cinder lake, a body of water 4 miles long by $1\frac{1}{2}$ miles wide. Many other small streams flow into the lake, but those mentioned are the only ones

of any size. The run-off of large areas seems to be accomplished by a slow seepage through the moss and muskeg, without any definite channels.

The fur trade is the oldest and still the most important industry of the Hayes River valley. Much of the country in the immediate vicinity of the river and its lake expansions has been exploited for so long and so intensively that the number of animals taken each year is much

PART OF EASTERN MANITOBA

smaller than formerly, but this is more than offset by the great increase in the value of furs. In the outlying districts tributary to Hayes river, there seems to be no decrease as yet in the number of skins taken.

No systematic examination of the water-powers of Hayes river has yet been made. In the part of the river above Knee lake there are several rapids and falls that could furnish considerable energy. Below Whitewater lake, the first expansion of the river, there is a descent of over 60 ft. in less than a mile of river. The average flow, however, is probably not very large. Below this

is a long narrow part of the river with several rapids; by damming the river below Hellgate rapids, power could be developed from these. Between Oxford and Knee lake several rapids occur and the lowest of these, Trout falls, has almost vertical descent of 15 ft. with possibly an additional 10 ft. in the rapids below. This should develop a fairly large amount of energy.

Much of the area has been burned over and the second-growth trees are still small. In well-drained areas trees attain a fair size, but in the poorly drained areas at some distance from the streams and lakes, growth is very slow and trees seem never to have attained a large size.

The rocks of the Knee Lake district consist of an ancient sedimentary and volcanic complex intruded by quartz-porphyry dikes and by batholiths of granite. These are probably all pre-Cambrian. Pleistocene deposits consisting of till and stratified sand and clay lie directly upon these old rocks, and, over much of the area, are overlain by beds of peat. So much of the region is completely covered by Pleistocene and recent deposits that it is difficult to determine the relations of the pre-Cambrian rocks.

The character and sequence of the rocks of the district are comparable with those in the district in which ore deposits have been found. Little prospecting has yet been done in any part of the Hayes River basin, and the veins found at Knee lake have been disappointing.

The heavy cover of clay and muskeg renders large areas underlain by promising rocks entirely valueless for prospecting. In some parts of the district the solid rocks are well exposed and search may be rewarded by the discovery of mineral deposits, but such parts do not constitute more than 2% of the whole area. Besides this handicap, the district lies at a great distance from transportation routes, and orebodies of only exceptional richness or unusual size would be worth considering. Notwithstanding these drawbacks the country in the vicinity of Knee lake must not be considered unpromising for mining. Some of the quartz veins have been shown to carry gold, although the amount in those examined is too small to be profitably extracted. Much of the area, even when the rocks are well exposed, has not been examined even casually and in those parts of the region as good chances exist of discovering orebodies as in similar rocks in other districts.

Assuming that mineral deposits are associated with igneous emanations, the rocks bordering the small intrusions of granite south-east of Cinder lake and east of the second narrows of Knee lake are the most likely localities for concentration of metallic minerals. Any of the rocks prior to the granite may possibly contain veins, but the brittle massive rocks, such as the lavas, are more likely to contain large and continuous veins than are the soft and heterogeneous sedimentary beds. The quartz veins that have been found to be auriferous occur in fractured quartz-porphyry dikes.

Claims have been staked at two places. One group occupies the eastern end of Magennis island, seven miles from the inlet of the lake, the other group is on a point

in Painkiller bay. A few other claims have been staked, but practically all the work done in the district is confined to these two groups. The Lucky Boy, Apex, Mother Lode, and McIntyre claims are located along the same mineralized zone, two claims lying on each side of it. At the eastern end, the zone lies in a dike of quartz-porphyry, but at the western end the dike is north of the quartz zone. In the altered and sheared dike are numerous intersecting veinlets of quartz one inch or less in width. The quartz in the schistose greenstone occurs in lenticular masses, the longer axis parallel to the direction of schistosity. The largest of the lenses uncovered is 25 ft. long and has a maximum width of 12 ft. Some pyrite occurs in the quartz; chalcopyrite is sparingly present in the wall-rocks. No gold is visible and assays of samples across the main lens at its widest part give only 0.09 oz. of gold per ton.

The claims on the point in Painkiller bay are the White Davidson, Tilden Smith, and O'Reilly. The point has been almost completely cleared and many trenches have been dug through the clay overburden. The rocks are greenstone conglomerate with chert and greenstone pebbles intruded by a quartz-porphyry dike. This dike has been fractured and in the fractures veins of quartz up to an inch wide have been deposited. The whole body of the dike was said to carry gold; but assays of samples of the quartz veins that seemed to be the most likely source of the gold show only traces.

GRADUATES from Australian universities will be given the opportunity to obtain a year's practical experience in the plants of the Electrolytic Zinc Co. of Australasia under the supervision of the superintendents of various branches according to the provisions of a plan adopted by the company. Holders of these cadetships, as they are termed, will have an excellent opportunity to gain a full knowledge of the plant in running, of commercial-scale metallurgical operations, and of labor conditions, and will be classified, at the end of the year, as follows: Class A: Specially good men, with personality for command and technical ability. These cadets will be marked for special advancement. Class B: Cadets with technical ability, but without power of command, who may be usefully employed in research. Class C: Cadets with power of command, but without high technical ability might be employed in routine operating. Class D: Remainder to be dispensed with. Cadets may take up either the metallurgical or the engineering side, but no distinct line will be drawn between the two. This scheme is, of course, quite distinct from that for awarding scholarships and bursaries to a limited number of picked university graduates, which has been subscribed to by a number of mining and metallurgical companies in the Commonwealth, including the Electrolytic Zinc Co.

RAISES AND WINZES used for man-ways should have ladders in good repair. Collars of winzes, raises, or man-ways should be protected by means of doors, railings, or bars.

Danger From Explosives Fume in Metal Mining

By D. HARRINGTON and B. W. DYER

*Two recent catastrophes in Western metal mines, in each of which three men were killed by breathing fume from explosives, have aroused keen interest among mining men not only as to the exact cause of such accidents, but also as to the best preventive measures.

In sinking the 45° inclined Marsh shaft near Burke, Idaho, on May 13, 1920, a round of holes containing about 60 lb. of 40% gelatin was blasted by miners on the night shift upon leaving at 11:30 p.m. It was customary for them to leave compressed-air blowers open at the bottom of the shaft until the compressor was shut-down shortly before midnight. Presumably this was not done on this particular night, as the fume was so heavy in the shaft-bottom on the morning of the 14th that at about 8 o'clock, F. L. Bergen, superintendent, and one of the shaft-men, on reaching the bottom, were overcome and fell from the bucket into the sump containing about six feet of water; and when two other men went down in the bucket a few minutes later to investigate, one also fell into the sump and the other was barely able to reach the surface. The three bodies were later recovered from the sump.

At 4:50 p.m., June 10, 1920, at the Dominion mine, Colville, Washington, a round of 11 holes containing about 15 lb. of 60% nitroglycerine was blasted in a 50° raise about 50 ft. above the main-tunnel level by the men going off for the night. In this mine it was the practice not to try to blow out the fume until just before the men on the shift went to work the next morning. Although no work was being done on the night shift, one of the raise-men, curious to ascertain the effect of the shots, at about 7:45 p.m., wandered into the mine (which was a tunnel only a few hundred feet long), and was missed by one of his companions an hour later. When three men tried to remove the body of the inquisitive miner, two of them also were overcome; later these two and the first man were removed from the point at which all were asphyxiated, which was practically at the foot of the raise.

In this case the explosive was $\frac{3}{4}$ -in. straight nitroglycerine, used because the ordinary $1\frac{1}{4}$ -in. gelatin was temporarily unobtainable, though the holes were drilled for the larger sized stick; the explosive, too, was about a year old. While two of the eleven holes missed fire, there was obtainable no evidence of burning explosive, but later, after firing these two missed holes, containing possibly three pounds of the explosive, a sample of air taken a few minutes after blasting, at the point at which the three men had been asphyxiated, gave 0.79% carbon monoxide, or sufficient to cause death after being breathed for a

few minutes. It was thought locally that the deaths were due to other gases, but analyses indicate strongly that carbon monoxide was responsible.

These accidents emphasize a danger daily confronting men working in metal mines and especially in small properties. In one case the dangerous fume was in a shaft, in the other in a raise, the deaths in the latter being, however, practically on the tunnel-level. Compressed air was the usual means for removing dangerous gases and in both mines it failed.

In neither case is there evidence of defective explosive or of bad methods of firing; hence the situations are practically such as may occur at any of our operating metal mines, especially those operating on a small basis, and the question arises as to possible prevention of such accidents.

The Bureau of Mines has been asked to attack the problem from various points of view; some companies having several mines and employing hundreds of men have numerous cases of 'powder gassing' annually, frequently with fatal results, and have asked the assistance of the Bureau in finding methods of firing explosives so that no poisonous fume will be developed; others wish experimental work along the line of developing a 'fool-proof' super-safe explosive such that irrespective of method of handling, and conditions, no dangerous fume will result; and still others, realizing the probability that dangerous fume will be generated irrespective of present-day precautions, wish information as to positive methods of removing dangerous fume.

Theoretically, there are in existence today explosives with constituents so balanced chemically that with complete detonation there should be no resultant gases of more potential danger than carbon dioxide, which, mixed with the almost invariably larger quantities of ordinary air present, would be diluted to such an extent as to be harmless. The Bureau of Mines has in several publications given data as to proper methods of blasting, selection of explosives, etc. However, numerous samples of air at faces in metal mines almost invariably reveal the presence of dangerous gases due generally to incomplete combustion, these dangerous gases being usually carbon monoxide and oxides of nitrogen. Dangerous percentages (upward of 1%) of carbon monoxide have been obtained at drift-faces after blasting with explosives of ammonium nitrate as well as gelatine base, detonated with No. 8 as well as with No. 6 caps, fired electrically as well as by fuse, tamped and untamped.

The most dangerous gas found in fume of explosives is carbon monoxide, of which quantities up to and over 1% are frequently found in the general air around newly

*Report of investigations. U. S. Bureau of Mines.

blasted faces, and frequently as much as 0.2 to 0.3% in air from piles of broken rock several hours after blasting. This gas gives headache when mixed with air in proportions as low as 0.05%, and is dangerous at 0.20% and quickly fatal when over 0.50%. Another gas sometimes found is nitrous oxide and its effect, while serious, is not likely to be so quickly fatal as that of carbon monoxide; however when dynamite burns instead of exploding, the nitrous content of surrounding air may be sufficiently high to cause death. Other dangerous gases, such as hydrogen sulphide and sulphur dioxide, may also be found in fume, but are rarely present in harmful proportions. However, straight nitroglycerine dynamite gives off several times as much carbon monoxide gas as gelatin or ammonium-base explosive, hence straight nitroglycerine should never be used in confined places.

It appears that at present there is no explosive used in metal mining, with any guarantee that formation of dangerous gases can be prevented, hence the one feasible preventive is effective ventilation.

It is significant that in 1919, the coal mines of the United States, which are compelled to give minute attention to ventilation, had but three deaths from suffocation from explosives fumes, although over 760,000 men were employed, or about three times as many as in metal mines. Metal mines too frequently place entire reliance on natural ventilation or on compressed air, and both are likely to be inefficient, dangerous, and, in the long run, costly. A compressed-air blower will rarely deliver to a working-face more than 100 to 150 cu. ft. of air per minute. The cost is 2 to 5c. per 1000 cu. ft. and there is danger that at least occasionally the compressed air may, through defective compressing, be charged with dangerous gases. Ordinary ventilation methods by mechanical fans produce air circulation at a cost of about 2 to 5c. per 1000 cu. ft. and, with proper supervision, will readily deliver several thousand cubic feet of air per minute to working-faces, instead of the 100 cu. ft. by compressed-air blowers. For dead-end faces of drifts, cross-cuts, raises, winzes, and shafts, small electrically-driven fans direct-connected to $\frac{1}{2}$ to 10-hp. motors force air through canvas tubing or galvanized pipe, and readily deliver 1000 to 5000 cu. ft. of air per minute, or 10 to 50 times as much air as can be obtained from compressed-air blowers and at much less cost. These small fan and canvas or galvanized-pipe units not only remove fume from the face, but if operated as blowers will keep a stream of moving air at the point where the machine-man or shoveler works. In hot mines especially, the worker's comfort and efficiency are greatly improved and his health and safety assured at least as far as explosives fumes are concerned. Managers of the larger metal mines now recognize this and many new mechanical ventilation units are found in the West.

THE MINING INDUSTRY of Russian Armenia is represented by 22 copper-ore, rock-salt, and pyrite enterprises, 18 of which exploit old mine workings. Seven copper smelters comprise the metallurgical industry of the coun-

try. The average annual production during the years 1911, 1912, and 1913 was as follows: 13 mines produced 154,900 metric tons of copper ore; 4 mines 10,000 tons of iron pyrite; 5 mines 25,400 tons of rock salt; and 7 smelters 6614 tons of copper. Armenia's output of rock salt and iron pyrite represents 100% of the production of the whole of Transcaucasia and its production of copper 69%. Before the War Russian Armenia's copper output represented 20% of Russia's total production.

Ozokerite

The largest domestic deposits of ozokerite are in Utah near Colton, Utah county, and Soldier Summit, Wasatch county, along the Denver and Rio Grande railroad, about 90 miles from Salt Lake City. During the War the Soldier Summit deposits were reopened, a new plant installed and production started on an important scale. The ozokerite occurs as a filling of brecciated zones in fissure veins in sandstones and shales. The veins vary in width up to 5 or 6 ft. and the ozokerite in the veins from mere films to 22 in. The ore from the mine is sorted, crushed, and subjected to a refining process. Several methods have been used, varying principally in mechanical details, but the underlying principles are similar. The ore is placed in steam-heated vats with water and raised to a temperature of 54° to 70°C. The wax melts and floats off as a liquid into cooling-vats, while the rock is removed either continuously or intermittently from the bottom. The impure wax is purified by a second boiling, and the tailing from the first tanks is re-treated, producing an impure wax which is later purified, a middling product which is returned to the first tanks, and clean tailing which is wasted. The purified wax is heated in an open tank to remove trapped moisture, and then cast or molded into blocks for market.

Ozokerite may be used either as the purified wax or as ceresine, which is made by further refining ozokerite. The wax may be purified by mixing with alkali and filtering through fuller's earth, animal charcoal, or magnesium silicate.

Ozokerite vaseline is made by filtering ozokerite through animal charcoal 12 to 30 times, and distillation with superheated steam at 250°C. for three or four hours. Ozokerite is used for the manufacture of wax figures, dolls, and candles; as a substitute or adulterant for bees-wax; as a covering to protect metals from moisture, acids, and alkalies; for making waxed paper; for lining barrels, kegs, and acid tanks; as a foundation for waxes, polishes, liniments, salves, and plasters; for imitation alabaster statuettes and decorations for confections; for artificial honeycombs, for making boot-blackening and polish, varnish, shoemaker's wax, and floor-wax; as a base for a variety of lubricants from axle-grease to gun-oil; in the manufacture of leather polish, sealing-wax, and pomades; and as electrical insulation. A very large and important use, which took most of the domestic output in 1918, was as an acid-proof coating for electrotypers' plates.—U. S. Bureau of Mines.

Care of Rock-Drills

By HOWARD R. DRULLARD

*Best results from hammer-drills may be obtained by giving close attention to two factors in drill maintenance. They are of equal importance; one is lubrication, and the other is care of the shank. With the exception of stoping-drills, most modern rock-drills require both oil and grease. The oil-ports are in the lubricator, on or behind the hammer-cylinder; the grease-port for the lubrication of the chuck-sleeve and rotating mechanism is on the chuck-end. Ordinary machine-oil is not adapted to rock-drills; a heavier more gelatinous oil such as castor machine-oil or liquid grease should be used. The lubricators should be filled once for every 12 or 14 ft. of hole drilled. Grease-guns should be used to fill the port in the chuck-end once a shift; a medium grease is well adapted to this purpose. Hard grease must not be put into the lubricator, as it will not flow through that part. Contrary to the popular belief, oiling a machine once or twice a shift does not provide sufficient lubrication; the drills should be oiled once for every 12 or 14 ft. of hole drilled.

The rotating handle of a stoping-drill is an oil-reservoir and is provided with a port for oiling. The rotating handle is packed with wicking, or similar material, which causes the oil to feed slowly from the handle to the other parts of the machine. Stopping-drills require oil at least twice a shift; lighter oils than castor, such as Arctic Ammonia, may be used.

Drills used in shaft-sinking can be oiled satisfactorily by placing a good-sized drop-sight lubricator on the station above and connecting it with the air-line supplying the sinking-drills. If this lubricator is properly filled and adjusted, a uniform oiling of the sinking-machines will be effected without the necessity of oiling the drills individually. The grease end should be filled at the station or on the surface before each drilling-period. The shift-boss should see that the machines are greased and also that the lubricators at the station function properly. The life of the air-drill hose is somewhat shortened by this method, as oil attacks the inner tube; but as some oil is always present in the compressed air, this is not a serious objection to the method.

When operating wet drills, the water-valve should always be closed before the air is shut off from the machine so that any water leaking from the water-tube will be exhausted from the machine. After drilling is finished, the machines should not be carelessly thrown aside, but should be carried well back from the face and placed in a clean dry place. Many experienced drill-runners stand the drifting and sinking-machines chuck-end up and pour a liberal quantity of oil into the chuck-end. This prevents rusting if there is moisture in the machine; also, the oil finds its way into the small parts, such as the rotating mechanism.

Stopping-drills are often stood in the opposite manner, that is, with the chuck-end down. Oil is then poured around the air-feed piston, often called the 'feed-bar'. The oil flows down the piston into the air-feed cylinder, keeps the cup-leathers soft and pliable and, if the leathers are somewhat worn, passes on into the other parts of the drill.

When machines have been in service for some time without being repaired, they should be sent to the surface to be cleaned and oiled. If this is not practicable, good results can be obtained by pouring 5 or 6 oz. of coal-oil into the air-hose, connecting it to the machine, and then running the drill for a minute or two. This will usually clean a drill quite thoroughly, but care must be taken to keep all lights away from the face for a few moments for, as the oil breaks up into very fine particles as it is exhausted from the machine, it forms an explosive mixture, which has been known to flash and burn the hands and face of the drill-runner. After the machine has been thus cleaned, the lubricators filled, and several ounces of oil poured in the drill-hose, the machine will be found to operate much more freely than before cleaning.

DRILL-SHANKS

The method of forming drill-shanks on a standard drill-sharpener is simple and quite generally understood. The shanks, however, must be accurately made and maintained at the dimensions specified for the particular steel. A variance of $\frac{1}{4}$ in. in length will often reduce the drilling speed of the machine 25%. Close attention must also be paid to the shape and location of the hole made to accommodate the water-tube. To avoid excessive breakage of water-tubes, this hole must be $\frac{5}{8}$ in. diam. and punched to the depth of at least 3 in. It must be in the centre of the steel and, after punching, should be counterpunched slightly to prevent a sharp edge forming that will cut off the water-tube. The shank, of course, should present a smooth striking-face.

The shank, when properly formed, is hardened. Sometimes this process is not thoroughly understood. The operation is simple, involves no delicate judgment of temperatures or high mechanical skill, can be learned by any intelligent blacksmith in a few moments, and makes a shank that will not batter, break, or damage the piston-hammers of the rock-drills.

The proper treatment of the shank begins in the forging. The steel must not be overheated, that is, it must not approach a white heat. The work of forming the shank should begin as soon as the steel attains a bright-red heat. The steel must not be allowed to 'soak' in the fire, as this causes scaling; an unduly high air-pressure in blowing the forge will also cause the steel to scale, and a scaled shank will not respond properly to the hardening process. After forming, the shanks should be annealed by being cooled gradually; preferably they should be covered with lime or ashes and allowed to cool.

Either fish or linseed oil is satisfactory for hardening, although other light oils are at times used. The quantity required is proportionate to the number of shanks to be hardened at one time; 5 gal. will suffice for the harden-

*A paper to be presented at the Lake Superior meeting of the A. I. M. & M. E. in August 1920.

ing of three or four shanks, but if considerable steel is being worked, 45 or 50 gal. are advisable. A rectangular tank in which the steel can be stood on end conveniently is generally used. A heavy screen should be placed 4 or 5 in. from the bottom in order to hold the steel above any water or dirt that may collect in the bottom of the tank. The oil must be kept free from any foreign matter, particularly water, for water collecting below the oil will over-harden any hot steel that comes into contact with it.

The shank should be heated to a cherry-red at the striking end, with the heat graduated to a dull red just beyond the collars, or lugs; or in the case of the shankless stoping-steel, to a point about 4 in. from the end. The shank is then plunged into the oil and allowed to cool thoroughly; the operation is then finished except for testing.

One thing must be borne in mind: each and every shank must be so hardened that it can be readily cut with a file. The shanks must be softer than the piston-hammers or damage to both will result. It is obvious that if two pieces of steel of approximately the same hardness are brought violently together, one or both will be damaged. If any piece cannot be readily cut with a file, it should be rejected and re-hardened and the oil tested for water. Care must be taken that too many shanks are not treated at one time and the oil over-heated; if the oil becomes hot, soft shanks will result. The often-used draw-temper water-method requires an extremely fine knowledge of color values, is seldom accurate, and is much slower than the oil method, therefore it should not be used. If the shanks are properly hardened, any well-made piston-hammer will take care of itself.

Tin, Lead, and Zinc Mining in Great Britain

An interesting report has been made by a committee appointed by the Board of Trade to investigate and report upon the nonferrous mining industry of Great Britain.

The production of black tin from existing mines and streams, all situated in Cornwall and Devon, amounted in 1918 to 6378 tons, which, in terms of metal (the black-tin concentrate from the mines is taken to contain 65% of recoverable metal, that from the stream works 46%) is 3% of the world's production and under 15% of the normal British consumption of the metal, taken at the pre-war figure of 27,500 tons per annum. The falling off in the production during the last 30 years, from close to 1500 tons in 1890, is due to several causes, the chief of which are the fall in the value of the metal in the period 1890-1898, impoverishment with increasing depth, exhaustion, and the increased cost of extraction and of pumping. It was accentuated during the War by the lack of development consequent to the labor shortage.

The future of tin mining in Cornwall depends in a great measure on the finding of new shoots by lateral development on the lodes now worked, or by cross-cutting

from existing workings to other known lodes, some of which in their shallower levels were large producers of copper. The work of mining geologists and engineers in the Camborne-Redruth area has indicated the probability that certain mines in this district, which were abandoned when their copper production failed, will be found to be valuable tin producers if developed at a lower level.

Lead mining is of great antiquity in the British Isles, dating back to the time of the Roman occupation; and for many centuries large quantities of lead ore were obtained from outcrops and shallow workings. Deeper mining, involving pumping, belongs to a comparatively late period, but was carried on extensively during the last century. Consequently, the more accessible and richer ore-shoots are now exhausted; and in general it is where natural difficulties hindered exploitation that the richer orebodies have been preserved for the miners of today. A notable example of this is the Halkyn district of Flintshire, where the lodes in the mountain limestone are so heavily watered that they could not be mined to any considerable depth with ordinary pumping appliances. The driving of a drainage tunnel, which was completed about 1886, enabled them to be worked down to 200 ft. above sea-level. A new tunnel has been commenced and would, if continued as projected, unwater the mines down to sea-level, thus rendering a large quantity of valuable lead ore available for mining.

The mining of zinc ore in this country is not so ancient as that of lead mining. The ore is chiefly blende, calamine being of little importance. It occurs associated with galena; but 'black jack', as blende is termed by the miners, was formerly rejected as a waste product, the first recorded production of zinc ore being in 1858. Much has been discovered in recent years by working over old dumps and by re-opening abandoned stopes where blende has been left on the walls of the lodes, or used as filling. The total production, however, is not large, and has fallen from 17,294 tons in 1913 to 9025 tons in 1918, the latter figure representing 5% of the present capacity of the home smelting works. In terms of recoverable metal (the zinc concentrate is taken to contain 35½% of recoverable metal) it represents 0.65% of the world's present production of spelter and about 1.6% of the pre-war British consumption of that metal. The present outlook for zinc mining, the committee states, is discouraging, since mines that are mainly dependent on blende production are not able to make a profit at current prices for the ore. The low price obtainable for home-produced blende is due mainly to the high smelting-costs prevailing, but the purchase by Government of the annual production of the Broken Hill mines of Australia was considered by many to be a contributing cause.

TUNGSTEN is obtained from various ores, such as wolframite, which is a tungstate of iron and manganese, and scheelite, which is a calcium tungstate. Ores are mined in Colorado, California, New Mexico, and in other places. The ore is usually reduced to the oxide, which is a yellow powder.

Standardization of Mine Work

*The application of time-studies to mining operations on any comprehensive scale, I believe, is new. The value of time-studies was first emphasized some years ago by Taylor and has been widely recognized in manufacturing and other productive industries, but aside from special cases has never been used in controlling or standardizing underground work. All time-studies at North Butte were made by the company's staff. The well-known methods in general use in manufacturing industries were employed, but it was considered best to have the actual work done by men of experience in metal mining and familiar with the particular underground conditions to be studied. The investigations were comprehensive. Every operation underground was timed and a careful record was kept of the figures. The data, which were quite voluminous, after critical analysis by Mr. Braly and his assistants, formed the basis of the standard of efficiency ratings now in use. The time-studies also suggested numerous improvements whereby individual work could be made more productive with little or no increased effort. A classification of underground labor into various kinds of work performed under present conditions is as follows: Miners, 15.7%; shovelers, 26.8%; trammers, 18.9%; timbering, 26.4%; powder-men, 2.3%; nippers, 2.1%; station-tenders, 1.8%; shaft repairs and shaftmen, 2.4%; draining and ventilation, 1.9%; top carmen, 1.3%.

The greatest difficulty in applying the results of these time-studies to actual operations was to find a simple method of recording the work of each individual workman. This was finally solved by the 'pictorial' record card devised by Mr. Braly. On this card, the letter A, for instance, represents setting up a machine and taking it down, including bringing up the machine from the drill-platform to the breast, bringing the column to the breast and setting it up, placing the machine in proper position, connecting both air and water-hose, oiling the machine, etc., all preparatory to drilling. Should the time-studies show that the proper time for two men to perform this is 40 min., if they perform it in 50 min. they are 80% efficient; if they perform it in 30 min. their efficiency would be 133%. Every operation in drifting and cross-cutting has been timed and is known, so that it is only necessary to record the operations done by any man underground for an entire day, add them together, and compare the totals with the standard in order to arrive at his efficiency for the day. Shoveling, tramping, timbering, and all other underground work were timed in the same careful and detailed manner.

In practice, the shift-boss makes out cards daily for the men in his crew and sends them to the office, where the factors are applied. The cards for each man are totaled weekly and the factors have been so worked that the units can be added directly on a machine without involving any excessive amount of clerical detail.

These cards are not only efficiency records, they are

instruction cards for the men and the shift-bosses. They also give the shift-bosses specific information as to what men in different positions ought to do; this is one of the most important results that has developed by the use of this system. Many shift-bosses are inclined to give some men too much work and not enough to others, not intentionally, but because they have not crystallized in their minds the exact amount of work a man should do. Further, there is recorded on the cards the supplies used each day in each working-face. This facilitates compiling; and it has been found possible to improve considerably the routing of supplies to points of use, and thus eliminate time lost because the men did not have their supplies within convenient distance. Stocks and the location of underground supplies are kept track of on tally-boards, on which supplies used each day are pegged up from the cards; the stocks are replenished without special requisitions from shift-bosses. Tally-boards are also used for compiling the output of ore and waste-rock shoveled, and other items of work done.

After having established the time-standards and installed the system of recording individual efficiency, a bonus-system was inaugurated under which underground men are paid a bonus based on efficiency rating in excess of 80% of the standard. All underground men are paid the standard rate of day's pay regardless of rating, but if they make a rating of over 80%, they are paid at fixed rates per point above 80%. This is an incentive for the men to study their jobs and co-operate in raising the efficiency of the whole organization. However, the primary object of standardizing the work is to educate the miner to conserve his effort and not waste it. Ordinarily it requires much less energy to do a thing right than to do it wrong, and the application of the standardized methods has demonstrated this. The standard methods introduced have resulted in increased efficiency, but it is believed that they have at the same time enabled the workmen to do their work more easily.

It was also found that inefficiency was frequently due to men not being placed to the best advantage. For nearly three years, employment has been in charge of the assistant superintendent instead of the individual shift-bosses. He interviews all applicants for work and furnishes the various shift-bosses, on their requisition, with such numbers of men as they require. Men who are recommended for discharge or who wish to leave are obliged to report to him; in many cases such men are transferred and retained as employees. Of men so transferred, about two-thirds have made good in their new jobs. Since establishing this system, labor turn-over has been reduced over one-half and the shift-bosses have found that they get a much better force of men than when they hired their men by selecting from those who applied each day. The policy does not contemplate or tolerate discrimination against any man who is, by no fault of his own, unable to make a high rating; the policy is to give any man who is willing to work a chance to do so, to place him where he can do his best, and to educate him in his work so that he can do it better.

*From a paper presented by Robert Linton at the Lake Superior meeting of the A. I. M. & M. E. in August 1920.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

ASBESTOS MINING IN THE GLOBE DISTRICT.

GLOBE.—October 10 to 16 has been designated as 'safety week' in the Globe-Miami district, according to a recent announcement. Special plans have been formulated and the goal has been set for a week without a single 'lost-time' accident. The cutting by the Old Dominion company of the Maggie vein on the nineteenth level is considered important. The vein is practically undeveloped and it has recently been found that the ore

Geological Survey have found valuable deposits of asbestos on the Fort Apache Indian reservation and also the San Carlos reservation. Although mining is not yet permitted on these lands, the Government is taking steps to have these deposits made available to meet an ever-increasing demand for the product. T. R. Drummond, president of the Superior & Boston Mining Co., together with several associates, recently had a narrow escape when visiting properties in the Dripping Springs valley. While driving through the sandy bed of a wash, where travel is rarely impeded, they were overtaken by

LONGFELLOW MINE OF THE ARIZONA COPPER CO. AT MORENCI

assays better than 5% and is therefore available for direct smelting. Operations are to be continued down to the twentieth level in order to secure drainage. The San Carlos Indian reservation is to be opened at once for prospecting. The western section is known to be especially rich in asbestos, generally found in localities so rough that aeroplanes or dirigibles have been suggested as means of bringing out the ore. It is reported that Arizona will produce this year as much asbestos as the total output of the United States last year. During the year 1919 the total quantity of asbestos sold in the United States was 1002 tons, nearly half of this amount being contributed by Arizona. Almost all the asbestos mined in Arizona comes from the region north and west of Globe, although promising deposits have been found in the vicinity of Grand canyon. Members of the U. S.

a cloudburst which lifted the Ford car in which they were traveling, and carried it along at rapid speed for nearly a mile, finally leaving the party stranded high and dry on a welcome bar. After pumping out the machine it was found possible to resume the homeward journey without assistance.

JEROME.—It is reported that Tom Collins and associates are prospecting the Verde Central group of claims, having a large tract of land under option. Mr. Collins, who is an expert miner, was instrumental in collecting the group of claims which originally comprised the Junction division of the Calumet & Arizona Mining Co., in the Bisbee district, and which forms one of the best portions of the property of this organization, and he hopes to be as successful in his development of the Verde Central group. It is announced that sinking will shortly

be resumed at the Dundee-Arizona, perhaps as soon as the first of September. It is believed that the country has been drained to such an extent that the company will no longer be troubled greatly by the flow of water which forced the suspension of sinking last winter, when the shaft had reached a depth of 810 ft. When the pumps were stopped the water rose to within 25 ft. of the main station on the 450-ft. level. In the last two months it has subsided fully 150 ft. Development of the Dundee's surface deposit of carbonate ore continues. As yet no decision has been reached regarding the character of the plant that is eventually to be installed to handle this ore.

BISBEE.—It is reported that the old Mellegren property at Tombstone has been purchased by Frank P. Cavanaugh, a mining engineer of New York, representing a new company which has been incorporated in the name of the Tombstone Silverfield Syndicate, and announcement has been made that mining operations with modern machinery will begin shortly. After 30 days of preparation, the Flux Mining Co. started operating the mill at its property at Patagonia last week. For the present the company will work on a high-grade lead-silver sulphide ore of which about 300 tons has been broken down ready to mill. Many more tons are reported in sight. Although the mill has not been in operation long enough to give accurate figures, the company estimates that it will be able to mill 30 tons per day with one shift operating the mill. This is expected to make about eight tons of concentrate to be shipped to El Paso for smelting.

JEROME.—Owing to the failure of the stockholders to respond to the proposal made by the directors that they subscribe to a bond-issue for the purpose of continuing the development of the property, the Jerome-Verde is being closed down. The pumps are being pulled, the mules hoisted to the surface, and all preparations made for a period of inactivity at the property.

COLORADO

RICH ORE FOUND NEAR GEORGETOWN.

ASPEN.—Electric power is to be substituted for steam at the power-plant at the portal of the Hope tunnel of the Hope M. M. & L. Co. and a contract has been signed with the Roaring Fork Electric Light & Power Co. A saving will be effected, as the haulage charge on coal will be avoided. The breast of the Hope tunnel is in the blue and brown lime formation containing some silver, lead, and zinc.

GEORGETOWN.—Tetrahedrite ore sampling 400 to 2220 oz. silver per ton has been opened up in a new shaft on the Ready Cash in the Williams Fork section at a depth of about 30 ft. by Teagarden and Taylor, well-known Georgetown miners. The operators are sacking ore to be packed on burros and plan the installation of a steam-hoist. The Silver Mountain mine, operated by the Nelson Leasing Co., is producing both smelting and milling ores. A force of men is remodeling the Payne mill at

Empire and a flotation unit is to be added. The American Vanadium Corporation has a force of men preparing for resumption of work on the Urad molybdenum group that it acquired from the Primos Chemical Company.

IDAHO SPRINGS.—The Gem Mining Co. has surveyed a route from the Frater Friend group to the Silver Age mill-site on the C. & S. road below the city, and a tram will be constructed for the delivery of ore to the modern mill that will be constructed. The Crown Prince company has miners employed in the Hecla tunnel. Sulphide ore containing gold is being developed. The Hiren Mining Co. has awarded a contract for 600 ft. of cross-cutting and drifting at the Lake property. The lateral will connect with the Frontenac workings and ventilate both properties. Cabins are under construction on Mount Kelso for the miners employed on the Decker-Jeffrey properties. The tunnel has cut a vein, 600 ft. from the portal, that carries smelting and milling ore. Operations are to be continued through the winter.

SILVERTON.—The Climax-Tip Top tunnel in Eureka gulch is being re-timbered and re-tracked and development resumed. The property owned by the Brensen estate has produced high-grade gold ore. New York interests plan development of the Ariadne and the management is now cross-cutting at the fourth level for the shoot opened on the three levels above. A winze sunk from the third level proved continuity of the ore, with a streak 14 in. wide sampling 1 oz. gold, 51 oz. silver, with some copper content.

DENVER.—John T. Burns, assistant secretary of the American Mining Congress, now here to arrange for the September meeting, is authority for the statement that a Standardization Conference will be held in Chicago on August 30, at which Charles A. Mitke, chairman of the Metals section of the Mining Congress, William R. Roberts, president of Roberts & Sheafor, construction engineers, chairman of the Coal section, and representatives of the Federal Bureau of Mines, National Committee on Standards, and the American Institute of Mining & Metallurgical Engineers will be present. Details of the proposed work will be arranged. The Standardization conference will, it is expected, occupy two or more days of the 23rd annual convention of the American Mining Congress to be held in this city in November.

MICHIGAN

FURTHER DECLINE IN COPPER PRODUCTION.

CALUMET.—A decrease of 710,854 lb. of refined copper is noted in the July production report of Calumet & Hecla subsidiaries. Total output was 8,312,025 lb., compared with 9,022,879 in June and 8,803,811 in May. Production for July follows: Ahmeek, 1,572,838; Al-louez, 262,400; Calumet & Hecla, 4,684,972; Centennial, 34,600; Isle Royale, 775,200; Osceola, 735,900; Superior, 85,800; White Pine, 160,315. Of the Calumet product, 1,168,093 lb. represents the output of the reclamation plant. Osceola and Superior are the only mines of the group to show an increase over June, when the former

produced 661,500 lb. and the latter reported an output of 32,200 pounds.

Copper continues to go out from the Lake region in small lots, practically all of which is being shipped eastward. Calumet & Hecla this week filled an order for 250 tons for a New England customer and 350 tons of ingot bars also went out for a Philadelphia firm. Only small amounts of Calumet copper are going to automotive concerns. Quincy and Copper Range are filling frequent orders from automobile plants but the sales are far below normal. The lull in export trade is indicated by the fact that no metal has been shipped to Great Britain for several months. Only one shipment has been made by Calumet to Germany this year and the only order of consequence for some months is that now being filled for France, consisting of slightly over 1500 tons.

Colony still is in vein matter, but for the past few days probably not in commercial 'rock'. Nevertheless the work is of value, as it establishes the dip of the formation. The south drift, which now terminates 150 ft. from the shaft, is in trappy ground and the east cross-cut continues in the conglomerate. It is the plan of the management to proceed with the cross-cut, carrying out original exploration plans, but another week or ten days may bring it into a new formation.

With the first indication of the restoration of former conditions in the metal-market, Wolverine will begin to develop and explore the several lodes that are found in its property east of the Kearsarge formation. Two or three veins, penetrated by diamond-drills and cross-cuts from various levels below the 14th, yielded ore in commercial quantities and the preliminary openings were

COMPRESSORS IN THE NEW ENGINE-HOUSE OF THE TONOPAH EXTENSION MINING CO.

Local companies do not expect much improvement in the market until foreign demand improves.

Mohawk's experiment with 'zinc-field' scrapers in its levels have been disappointing and until a device that is less cumbersome is perfected no further attempt to utilize it will be made. The employment of stope-scrapers, however, is a splendid success and they are a permanent fixture in the Mohawk and Wolverine mines. They are operated by two men and perform the work that four to six men formerly did by hand shoveling. Mohawk's openings keep abreast of those of a year ago, while the yield continues at 22 or 23 lb., with occasional shipments of 'mass' boosting the grade to 25 lb. or better. With the present small force, compared with that employed in past years, no attempt is being made to open the fissure in No. 4 shaft and this will be left for future years. This vein, originally opened on the 22nd level, south, of the No. 4, contains considerable 'mass' and warrants extensive work as soon as conditions permit.

The raise in the west cross-cut of Mayflower-Old

of such character that extensive work on them will be done just as soon as the step is warranted. The showing in an amygdaloid on the 28th level was particularly promising and it is probable that the first development work will be on that lode. There will be no let-up in operations on the Kearsarge vein and by the time all of the arches and backs are removed it is expected reserves in other parts of the mine will have been determined. In the event the showing fulfills predictions, Wolverine's life will be prolonged. It was with the intention of developing new ground that the management decided that the shaft-pillars would not be removed, so as to keep the shafts intact. The pillars contain thousands of tons of high-grade rock, for they are 90 ft. square, extending to the bottom levels from the surface.

Whie Pine Copper is preparing to suspend operations and at present only a few men remain on the property. This decision came as no surprise, for the constantly rising costs of labor and supplies, together with the steady decline in output, left no alternative. For the

past four or five months a force of only 150 men has been employed and production dropped from 285,000 lb. in March to 160,077 in June. White Pine is a mine that presents different problems and requires more modern methods than any other property in the district. Due to the fine character of the copper in the Nonesuch lode, flotation and re-grinding have been used successfully. The rock is low in grade, in fact so low that it is stated that the mine can operate successfully only on a quantity basis. It is a subsidiary of Calumet & Hecla.

NEVADA

RECO DIVIDE CO. IS PROSPECTING NEAR WINNEMUCCA.

PARADISE.—The Reco Divide is prospecting 17 claims adjoining the old Spring City mine that were acquired by location. A shaft has been sunk 35 ft. in a quartz vein 10 to 40 ft. wide, and small seams of ore assaying 40 to 50 oz. silver and 40c. in gold have been found. The Reco first had an option on the Spring City, in which there was said to be good ore under water. The Spring City has a production record of \$3,000,000 net, made in the early '80s, but the ore-under-water rumors were scouted by J. B. Kendall, president and manager of the Reco, and work was stopped after one carload of ore had been shipped through Winnemucca, 50 miles distant. Kendall, formerly mine superintendent for the Goldfield Consolidated, said all he had ever found under water was fish. He estimates that a 1000-ft. tunnel driven in quartz with hand-steel by the Spring City in the '80s cost \$150 per foot. The ore was hauled to Martin creek, 12 miles distant, and milled. It now costs \$23 per ton to haul supplies from Winnemucca. Kendall has a good opinion of the district. The formation at Paradise is porphyry and slate. The Reco is developing a gold prospect at Spanish Flat, 20 miles from Kirby, a station on the Southern Pacific in Humboldt county. A 50-ft. tunnel is being driven to cut at a depth of 60 ft. a vein in which rich ore was found on the surface. The formation is lime shale, and Kendall has little confidence in the district. The Reco is backed by New York men for whom Kendall is trying to find a promising prospect.

ALLIED.—The Allied Mining & Milling Co. has at the mine machinery for a concentrator that is expected to treat 40 to 50 tons of lead-silver ore daily. The wagons in which the machinery was hauled returned to Goldfield loaded with 45 tons of ore assaying 60% lead and 15 oz. silver, according to David Trepp, manager. The construction of the plant is in charge of George S. Wardell, formerly mine superintendent for the Alto and East Divide companies. The manager says that conditions are excellent and that a raise from the 110-ft., or second level, has been driven to the surface in ore 4 to 15 ft. wide and assaying \$40 for this width. This shoot has been opened for 100 ft. on the second level, according to Trepp.

MANHATTAN.—A 150-ft. winze is to be sunk from the 800-ft., or bottom level, of the White Caps to determine the position and condition of the ore-shoot before sinking of the shaft to 1000 ft. is started.

SPANISH BELT.—A five-mile electric-power line has been completed to the Spanish Belt and it is expected to have a 50-ton mill and an electrically-driven air-compressor working within six weeks, according to Jules V. Barnard, president of the company. The mill will be built at the main tunnel, which is to be continued 150 ft. to connect with the shaft-workings.

GOLDFIELD.—The winze from the 910-ft. level of the Spearhead has been sunk 170 ft. and it is being continued. From the 130-ft. point it has been in the foot-wall of the vein and at the present depth seams 18 in. wide and assaying 80c. in gold are being cut. The last assays taken in the vein, at 130 ft., gave a return of \$7.90 for a width of eight feet.

WEST DIVIDE.—The raise from the tunnel level of the West Divide is 40 ft. high. At the 65-ft. point a cross-cut will be driven to the vein, according to L. L. Patrick, manager. The Occident Divide, owning eight claims adjoining the West Divide on the south-west, has started selling stock to raise funds for sinking a shaft. There is exposed in a 70-ft. inclined shaft sunk by former owners an 18-in. seam of ore that assays 80 to 120 oz. silver. The officers of the company are R. S. Wilbur, superintendent of the Spearhead in Goldfield, president; F. E. Sholtz, one of those who sold the Bell claims at Quartz mountain, vice-president; R. T. Armstrong, secretary and treasurer. H. F. Bruce, formerly manager for the Kernick companies at Divide, is a director and is consulting engineer.

TULE CANYON.—The cross-cut on the 200-ft., or bottom level, of the Ingalls has been driven 25 of 70 ft. necessary to reach the vein. The work is being done under contract with machine-drills and the cross-cut is being advanced 4 ft. daily. Whether the sale will be concluded depends on what is found at this depth.

UTAH

MINING COMPANIES PROTEST INCREASE IN FREIGHT-RATES.

SALT LAKE CITY.—A protest on behalf of the metal-mining companies against an increase in freight-rates, especially on low-grade ores, was begun on August 20 before the Public Utilities Commission. H. W. Prickett, manager of the traffic bureau of Utah, introducing witnesses to show that if such raises are permitted, it may put many low-grade ore shippers out of business. A. G. Mackenzie, secretary of the Utah chapter of the American Mining Congress, explained that freight-rates have a great deal to do with mining costs, as Utah is a low-grade-ore State. Testimony was given showing that an increase in freight-rates is a double burden to the mines, as the rate itself is not only raised, but the smelters also increase their rates, as a result of the increased cost of coal, limerock, and other supplies. After the freight increase on June 25, 1918, Mr. Mackenzie stated that the smelters raised their rates on smelting ores from 50c. to \$1 per ton. Figures were presented, showing that in 1917, there was mined in the State 15,358,481 tons of ore; in 1918, 14,705,718 tons; and in 1919 about 6,427,000 tons, the decrease being attributed to the mounting costs

of production and adverse metal markets. The values of the above tonnages were given at \$99,328,155 for 1917, \$86,047,597 for 1918, and \$45,438,985 for 1919. Mr. Mackenzie further stated that as a result of the adverse conditions, many Utah mines had been forced to ship high-grade ores, either avoiding the mining of low-grade ore, or throwing it upon the dump; that 138 small producers, who shipped a total of 1,058,244 tons in 1918, had been compelled to suspend shipments on account of the increase allowed in June of that year. All witnesses examined were agreed on the fact that any advance in freight-rates would be an unjust burden on mine operators, especially upon those who ship low-grade ores, and would undoubtedly result in the closing of many of the smaller properties.

GOLD HILL.—The Western Utah Copper Co. has en-

per, and thereby enable the company to sell the gold and silver direct to the mints. Recently a shipment of 30 tons of bullion was made to an Eastern refinery.

Exploration work being conducted at the Emerald mine, adjoining the Mammoth, the Centennial-Eureka, and the Grand Central properties, is meeting with encouraging results, according to officials. Development is being done on the 1000-ft. level, at which depth it is the intention to open up the north-south break which has been so productive in the Eagle & Blue Bell and Grand Central properties. This break can be traced, it is said, for a distance of 1500 ft. on the 'Diamond' claim. On the western side of the property, the ore-zone which has been productive in the Centennial-Eureka mine, can be traced across the Emerald ground for 3000 feet.

Development work is going ahead in a satisfactory manner at the Tintic Paymaster property in the northern part of the district. At the present time, a station is being cut on the 350-ft. level, preparatory to sinking a winze from the east drift, which is in a distance of about 500 ft. This winze is being sunk for the purpose of following a small vein. At the Selma Mines property, which adjoins the Tintic Paymaster on the south, work has been resumed and two shifts are employed in sinking the shaft, which now has a depth of 250 ft. At the Eureka Bullion property, small bunches of ore in the north drift on the 800-ft. level have been found, and a winze is sunk for further exploratory work. Within the next 30 or 40 ft. is expected to be able to deter-

DALY-WEST MINE AT PARK CITY, UTAH

tered into a new contract with the American Smelting & Refining Co., which will permit the production of its mine to be increased to three times the present output. During July the company shipped about 3000 tons of lead ore, and new contract calling for an output of 300 tons per day. It is estimated that there has been developed about 150,000 tons of low-grade lead-silver ore. All of this tonnage is above the 750-ft. level, the deepest in the mine. In addition to the lead ore, there is a large tonnage of iron fluxing-ore developed, and a low-grade copper-ore deposit.

EUREKA.—The Tintic Milling Co.'s plant is not operating at capacity on account of shortage of ore, an average of only about 150 tons being treated daily. One shift is employed in the crushing-department, while three shifts are required in the leaching and roasting-departments. At present some changes are being made in the precipitating and refining sections of the plant which will make it possible to separate the gold and silver from the cop-

mine the extent of the showing. John M. Bestelmeyer, manager for the company, states that the shaft is now at a depth of 900 ft., and a winze has been sunk from the 900-ft. level to a depth of over 400 ft. Within the next month, sinking of the winze will be resumed.

PARK CITY.—An important find has been made at the property of the Keystone Mining Co., according to Andrew Hurley, superintendent. The new orebody is on the K. K. Level No. 3, and since the vein was broken into, a drift 20 ft. long and a cross-cut of the same distance have been driven, all in ore averaging \$75 per ton. Another network of mineralized fissures has been cut by the Spiro tunnel, being driven by the Silver King Consolidated to develop its holdings at depth. The fissures heretofore penetrated by the tunnel have been cross-cut almost at right-angles. The newer veins are coming in obliquely, with a south-west trend. The territory now being pierced by the Spiro tunnel adjoins that of the Silver King Coalition company.

BRITISH COLUMBIA

EMMA MINE AT NELSON IS AGAIN PRODUCING.

HAZELTON.—Encouragement of the production of gold is a problem which is giving the Provincial Mines Department some concern. The amendments to the Placer Mining Act passed at the last session of the Legislature reducing rentals and other expenses attached to leases, and permitting the payment of arrears annually in comparatively small amounts, were aimed to making it easy for those really desirous to operate, and at the same time squeezing out those who have been holding merely for speculation. Attention now is being turned to a more direct, and perhaps a more practical, form of aid. J. D. Galloway, resident engineer with headquarters at Hazelton, has been authorized to continue Keystone-drilling operations on the placer areas at Harpers camp. This work was started last year, but for various reasons could not be finished. An expert crew of men has been engaged and operations have been under way for some weeks. Mr. Galloway estimates the amount of gold taken out of this area at from \$500,000 to \$1,250,000. It is pointed out that the character of the gold taken from the ground was uniformly 'fine, flat, and well worn', making it clear that it had traveled some distance and probably had its origin at some unknown point far up the Horsefly river.

TRAIL.—Four smelter employees were seriously hurt recently while at work in the copper-refinery of the Consolidated Mining & Smelting Co. All were burned about the face, and one, Gordon O'Connor, may not recover his sight. Molten copper splashed between the molds and into running water used for catching the drip. The copper was shot 40 ft. into the air. Ore receipts at the Trail smelter of the Consolidated Mining Co. for the week July 21 to 31 aggregated 12,862 tons and for the week August 1 to 7, 10,221 tons.

NELSON.—The Emma mine of the Consolidated Mining & Smelting Co. will resume operations immediately with a force of 50 men. This property formerly shipped about six cars of ore per week, but work ceased last year when production was discontinued at the Rossland mines. Now that the latter have resumed, the ore of the Emma is required, as it makes a good flux for the product of Rossland. It is understood that its output will be about the same as before. The ore is low-grade gold, silver, and copper.

VANCOUVER.—The Liberator Mining Co. has been formed to take over and operate the Emancipation mine, situated on the western slope of Coquihalla valley, opposite Dewdney creek. The consideration is \$60,000 in cash and \$100,000 in shares. In the Canadian Geological Survey report, which recently has been published, Charles Camsell, deputy-minister of mines, describes this property as follows: "The first work on this property was on a big quartz vein carrying a little gold. Later work, however, was confined to a high-grade vein near the hanging wall of the larger vein. On this a tunnel has been driven 220 ft., with a cross-cut 80 ft. in length to the right at a point 70 ft. from the portal. A raise to the surface and a winze 50 ft. deep were made on the ore-

shoot. The raise and winze supplied all the ore shipped, namely, 90 tons, which yielded \$35,000. The vein carries pyrite and arsenopyrite, some enargite, and much free gold. The gold is associated with both minerals and with them impregnates the country rock adjacent to the vein. Polished specimens indicate that the gold was introduced later than the pyrite and arsenopyrite."

SLOCAN.—Lessees on the No. 3 level of the Rambler-Cariboo mine have struck a one-foot vein of practically clean galena, assaying 71% lead and 370 oz. silver per ton. The discovery was made 450 ft. below the outcrop, with virgin ground above, so if the vein holds in size and richness the men have a bonanza.

ONTARIO

ONTARIO MINING ASSOCIATION MEETS AT SUDBURY.

COBALT.—Favorable developments in the Gowganda, South Lorrain, and Elk Lake districts, are reported, while at Cobalt the result of work on some of the newly-opened properties is also adding to the number of producers. At the 350-ft. level of the Bailey Silver mines a shoot of high-grade ore has been cut in which the silver content ranges from 2000 to 4000 oz. per ton. Further work will be necessary before the extent of the ore-shoot can be determined. The Keeley Silver Mines in South Lorrain is estimated to have close to \$1,000,000 worth of ore in sight. One shoot has a width of from 4 to 5 ft. and averages from 30 to 100 oz. of silver per ton. This ore-shoot is about 150 ft. long. In the meantime the work on the new mill is proceeding satisfactorily, the building itself being completed and the work of installing the machinery progressing. The mill will be ready to operate during the last quarter of the year and will treat about 80 tons of ore per day. During the third week in August a meeting of the Ontario Mining Association was held in Sudbury. About 90% of the mines of the Province were represented. This newly organized body, with a paid secretary and supported by the leading mining men, is looked upon as likely to become one of the most influential organizations in Canada.

PORCUPINE.—The McIntyre company has purchased the Blue Diamond Coal Mines Ltd., of Brule, Alberta, the property comprising an area of about 3300 acres, which is producing over 500 tons of steam and coking-coal daily. The company is capitalized at \$1,500,000. The McIntyre has also obtained an option on the Canadian Coalfields Ltd. in the same vicinity, capitalized at \$10,000,000 and covering a much larger area, which is stated to contain anthracite. J. P. Bickell, a McIntyre director, states that plans are under way for the immediate development of the coal mines and that equipment has been ordered which should increase the daily capacity of the Blue Diamond to about 2000 tons.

Regarding reports as to a possible merger of the Kirkland Lake, Orr, and Teck-Hughes mines, Frank L. Culver stated that a suggestion of that kind had been made, but that the terms of such an amalgamation had not been discussed, and the proposal would only receive consideration on a basis of actual values.

THE MINING SUMMARY

THE 'PORPHYRIES'

The extreme dullness prevailing in the copper industry since the buying movement which ended last March, was sharply reflected in the reports of the so-called porphyries—Utah, Chino, Ray, and Nevada Consolidated—for the second quarter of 1920. Excepting Chino, all had to dip into surplus to meet dividend requirements; and Chino just skipped by, having earned a net profit of 38c. per share against the period's dividend of 37½c. The relatively good showing made by the porphyries in the first three months of this year, however, was a good offset to the lean earnings of the second three months. Utah with net profits of \$3.14 per share for the first six months earned its dividend of \$3 per share; Chino earned nearly twice its dividend, and Ray earned a margin of 14c. per share. Nevada Consolidated was the exception, showing net profits for the half year of only 30c.; dividends called for 50c. per share.

In the matter of costs, however, three of the companies showed reductions. Nevada Consolidated's cost averaged 15.56c. per pound, or 5½c. less than in the preceding quarter. This was due to an exceptionally heavy credit to operating expenses having been received in the shape of a substantial sum from the Nevada Northern railway. Ray reduced its cost 1c. per pound, and Utah made a fractional discount from the previous three months. Chino, however, showed an increase in cost of 1½c. per pound. This was due to the higher iron content of its ore causing a lower yield of copper. Indeed the yield was less than for many months, the average for the quarter being 23.20 lb. of copper per ton against 25.66 in the preceding quarter. The tabulation below pictures earnings and costs in the second quarter of this year compared with the first, together with the dividend rates of the four companies:

	Net per share		Current dividend	Cost	
	Second quarter	First quarter		Second quarter, cents	First quarter, cents
Utah	\$1.38	\$1.76	\$1.50	11.77	11.93
Chino	0.88	0.93	0.37½	15.28	13.91
Ray	0.24	0.40	0.25	15.34	16.30
Nevada	0.19	0.11	0.25	15.56	20.72

The average price received for copper was considerably less than in the first three months. Under the policy of the porphyries of inventorying unsold copper at 13c. per pound and with this figure and the actual sales-price striking an average, it is impossible to deduce the actual selling price they received. The reduction in the carrying price in the second quarter is from 3½ to over 4c. per pound and is clear testimony to the lean business prevailing during the period. A comparison of sales-price averages of all four companies follows:

	Second quarter, cents	First quarter, cents
	Second quarter, cents	First quarter, cents
Utah	18.20	21.99
Chino	18.17	21.88
Ray	18.42	21.96
Nevada	18.50	22.66

CALIFORNIA

Nevada County.—A new tube-mill is being installed at the Alta-California gravel mine near Washington. Satisfactory clean-ups have already been made with antiquated machinery. C. W. Girton is manager and the property is being paid for out of royalties. The water is out of the 1100-ft. shaft at the Idaho-Maryland at Grass Valley and the drain-

ing of the 1000-ft. incline will soon commence. The shaft of the Greenman quartz mine on Canada hill, owned by the Mayflower Consolidated Company of Omaha, is being sunk rapidly. The old shaft was 300 ft. deep and since renewing operations has been advanced 30 ft. The company will sink 150 ft. and there explore the vein with two drifts. It is a 2-compartment shaft, 6 by 14 ft. The equipment consists of an electric hoist, compressor, and two pumps. A test is being made of a small lot of ore at E. D. Ott's sampling works in Nevada City preparatory to making an application for permission to sell 100,000 shares of stock. Charles Dow is superintendent.

The mining companies at Grass Valley are agitated over an order issued yesterday in San Francisco by H. G. Butler of the State Railroad Commission, curtailing electric energy 20% in central and northern California except for agricultural and domestic purposes. The superintendents are making an effort to keep the mines in operation. Power is furnished by the Pacific Gas & Electric Co. and is distributed principally among the Empire, Idaho-Maryland, Allison Ranch, North Star, Alcalde, and Sultana mines at Grass Valley and at the Montana and Mayflower near Nevada City. The proposed reduction of 20% means that actual mining will practically cease until the fall rains. Every effort is being made, however, to prevent the order from being carried into effect in this district. The removal of all underground material in the Champion mine near Nevada City was completed yesterday. The hoist at the Providence shaft will be removed to the Empire mine at Grass Valley. The property has gone through the experience of closing down only to be later re-opened several times. There are rumors of a bond to be taken on all the company's holdings in the vicinity.

Sierra County.—The plant at the Independence mine near Alleghany, consisting of a 5-stamp mill, hoist, compressor, boarding-house, and other buildings, was completely destroyed by fire on August 13. Shortly after the fire started two explosions were heard in the mill suggesting the possibility of incendiary origin of the fire. The property was recently bonded by W. H. Griffith, supplies had commenced to arrive and preparations were being made to unwater the shaft and develop the mine. The raise in the upper tunnel in the City of Six mine near Downieville is up more than 100 ft. and is in excellent ore. A raise is also going up in the lower tunnel as well as a cross-cut. It is the intention to drive this tunnel ahead 700 ft. to determine the length and depth of the orebody in the upper workings. Hugh McCormick is temporarily in charge.

IDAHO

Coeur d'Alene.—With the Nabob mill in operation and its underground work showing up well, and increased activity in a number of other properties, the Pine Creek district is beginning once more to attract attention. Good reports from the development work under way on the Sidney mine, where a drift on the vein has been driven 150 ft. east of the shaft, show a well-mineralized lode carrying lead, silver, and zinc. This drift will reach its objective in another 100 ft., where it is expected to open a body of ore previously disclosed in the upper levels.

Work of the Red Monarch Mining Co. will be resumed

soon. It is expected either to drift or sink, or perhaps both, on the vein that was struck when the 4000-ft. adit was driven two years ago. The vein is at 3000 ft. and is one of three promising lodes cut by the long cross-cut. The company has a compressor-plant and other machinery for development.

The production of lead, zinc, and silver from the mines of the district is greater to date than for the same period of 1919. In 1918, the mines of Idaho produced 294,695,993 lb. of lead, but the total output in 1919 was about 184,079,000 lb. The output of recoverable zinc in Idaho decreased from 45,161,172 lb. in 1918 to about 16,565,000 lb. in 1919. If the Callahan Zinc-Lead Co. continues to ship zinc ore and concentrate at the present rate, about 3500 tons per month, the output of zinc in 1920 will be larger. The production of silver in Idaho in 1919 was about 7,700,000 oz., valued at \$6,340,000, the lowest output for the last three years. The average annual output for the last ten years was 9,730,180 oz. The producers of silver-lead ore in the Coeur d'Alene district are making larger shipments than in 1919, especially the Bunker Hill, Morning, Hecla, Hercules and Tamarrack, and Custer mines.

MISSOURI

Joplin.—The Butte-Kansas Mining Co. has begun the operation of its new mill, which was erected near the site of the old plant that was seriously damaged by a cave-in at the mine on June 1. Operation continued for a full 10-hour shift, during which time a carload of concentrate was made. All machinery in the plant worked perfectly and there was not a hitch anywhere. Following the cave-in on June 1, preparations were made to re-build immediately and construction work started June 17. The new plant is of 400-ton capacity. The company has continued development of its lease and as a consequence continuous production is assured. One of the new holes shows a face 65 ft. thick that averages 19½%. Another hole has a face of 210 ft. of 9½% ore.

MONTANA

Butte.—Details of the compromise agreement between Anaconda company and the W. A. Clark interests whereby Anaconda gives to the latter a portion of the Emily vein under the surface of the Pilot-Butte claim have not been disclosed, but it is known to be a notable victory for the Clark interests. A vein apexing in the Elm Orlu claim, the prior location, was found to unite with the Emily on its dip at about the 2400-ft. level of the Pilot-Butte, where the ore-body has a width of approximately 50 ft. with the grade of ore ranging up to 6% copper, with some silver. Anaconda, some years ago, instituted suit against the Pilot-Butte, claiming the Pilot-Butte's chief fissure, the Emily, on the ground of extra-lateral rights, purchasing the property later for \$1,125,000. Certain interests that had been connected with the Pilot-Butte asserted that this sum was insufficient, in view of the size of the orebody disclosed.

MEXICO

Dispatches dated August 23 state that Pedro Zamora has released six of the Americans who were kidnapped recently by him in the State of Jalisco, but is holding one American, W. A. Gardner, superintendent of the Esperanza mine, for a ransom of \$100,000 and W. B. Johnson, a British subject, for \$50,000. Charles Hoyle, manager for the Esperanza Mining Co. at El Oro, and Mrs. Hoyle, have been released and are now safe at Penas, on Banderas bay. The names of the other four Americans set free are given as Dietrich, Gillis, Culvert, and Nels. These four are at Mesa del Corazon. J. C. Bryden, representing the Esperanza company in Mexico City, today said nothing regarding a ransom for the Americans captured had been received, but that the money was ready for payment when the demands were presented. He explained the presence of Hoyle and the other Americans in Cuale, where they were captured, by saying that they left El Oro to inspect a mine in that vicinity.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Oscar Lachmund is at Canton, China.

Andrew W. Newberry has returned from London to New York.

Arthur J. Stewart has moved from Cottage Grove, Oregon, to Los Angeles.

A. C. Block, recently of Brownwood, Texas, is at San Diego, California.

H. R. Bischoff has gone from Stillwater, Minnesota, to Larder Lake, Ontario.

James O. Greenan, lately at Mina, Nevada, has gone to Dawson, in the Yukon.

D. D. Irwin has become superintendent for the Moctezuma Copper Co. at Nacozari, Mexico.

Donald F. Irvin has returned to San Francisco after an extended stay in South America.

Lewis A. Levensaler has gone to Nome, Alaska, and will not return to Seattle before October.

Felix McDonald, superintendent of mines for the Inspiration Con. Copper Co., is visiting California.

J. P. Montague, formerly superintendent of the Big Pine mill, Manhattan, Nevada, is now at Tonopah.

A. W. Rogers, representing the Central Mining Corporation, has returned from New York to London.

F. C. Schrader, of the U. S. Geological Survey, is making an examination of the Jarbidge district, Nevada.

C. T. Ulrich, secretary for the Kennecott Copper Corporation, is making a trip to Western mining camps.

J. D. Shilling, general superintendent of the Utah Copper mine, is spending his vacation at San Diego, California.

F. L. Bosqui, now residing in New York, paid a short visit to San Francisco, in the interest of Charles Butters & Co., London.

F. L. Stack has left the Cia. de Santa Gertrudis at Pachuca, Mexico, to join the staff of the Chile Exploration Co., in New York.

Y. Nakayama, metallurgical engineer with the Furukawa Mining Co. of Japan, has been visiting mining and metallurgical plants in Utah.

F. R. Raiff, traffic manager for the American Smelting & Refining Co., with headquarters in New York, has been in Utah and Idaho recently.

Ernest G. Ashby, chief accountant for the Julian Alaska Mines Co. and auditor for the Algonian Development Co., has returned to Montreal.

Harry P. Hill, formerly foreman of the Clay mine of the Arizona Copper Co., at Morenci, Arizona, has accepted a position as superintendent of the El Bordo group of mines, which is controlled by the Santa Gertrudis company, of London.

Spencer W. Clawson, pioneer mining engineer, died at his home in Los Angeles on August 15. Mr. Clawson came West in 1880 and settled in Arizona. He became identified at that time with the Contention mine in Tombstone and later was associated with some of the biggest mining enterprises in the country. For 23 years he was manager of the Copper Queen Consolidated in Bisbee and then he went to Los Angeles and opened offices as a consulting mining engineer. He returned to Arizona as consulting engineer to the Arizona-Michigan Co. and two years later went to Pinal, Mexico, in the interests of a gold mining company. He was driven from that country by Villa and again returned to Los Angeles.

THE METAL MARKET

METAL PRICES

San Francisco, August 24

Aluminum-dust, cents per pound.....	85
Antimony, cents per pound.....	8.50
Copper, electrolytic, cents per pound.....	19.00

EASTERN METAL MARKET

(By wire from New York)

August 23—Copper is inactive but firm. Lead is quiet but strong. Zinc is moderately active but higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

"Were shipments of great quantities of gold possible, even if that were desirable," said F. R. A. Shortis, vice-president of the Guaranty Trust Co., "the decline in Sterling exchange would be arrested immediately; but although Great Britain is not in a position to liquidate her indebtedness to America in gold, she holds abundant tangible assets, which America could have today, as good in intrinsic value as the American securities which the British people have already sold back. If the United States would adopt the policy of purchasing securities now held by Great Britain to the degree that Great Britain invested in American securities before the War, estimated at \$10,000,000,000, the difficulty would be solved at once. I am aware, however, that while American securities always appeal to British investors, British securities of equivalent intrinsic value have not appealed to American investors. For this there have been certain well-defined reasons, including the field for domestic investments presented by the development of this newer country. I am aware also that American farmers and manufacturers and merchants require money, rather than securities, for their purposes, and that bankers are required to keep their depositors' funds liquid, but nevertheless it is unfortunate that the investing public of this rich country cannot, for the time being, be induced to invest in foreign securities.

"The debt of Great Britain to the United States today approximates \$5,000,000,000, made up of \$772,000,000 of Government loans and of \$4,280,000,000 of other credits on behalf of the British government. Until the loans that are placed in this country mature, they will not, of course, affect the exchange situation. Sterling exchange is declining because British exports are not at present sufficient to pay for current imports. The recent decline is due to the large supply of grain bills offered. So far, very little cotton exchange has been offered.

"This decline in Sterling exchange will operate automatically to increase the cost of British goods and thus prove to be a blessing in disguise. It will, on the other hand, stimulate British exports to the United States. While the curtailment of American export trade, because of a low Sterling exchange, may be a hardship for the time being, we must recognize that the British are by this method adjusting their international account with Americans and that eventually this will be to America's advantage as well as to Britain's. Until the British are able to adjust their indebtedness to the United States, the decline in exchange will provide the only effective method of forcing Great Britain to economize, and the more the exchange declines, the greater will be the effect.

"The restriction of imports into Great Britain and the encouragement of exports are not, however, the only economic forces thus brought into play. Because of the low Sterling exchange, investments in British securities are made exceptionally attractive. Under present exchange conditions these securities can be bought at a discount, in fact, at a discount which is exactly the same as the premium which British purchasers have to pay on commodities imported from the United States. Should the American investor disclose a disposition to take advantage of this situation, he could have a wide choice of gilt-edged investments, including railway debentures, municipal bonds, and many other securities based on tangible assets."

Foreign quotations on August 24 are as follows:

Sterling, dollars:	Cable	3.55 1/2
	Demand	3.56
Francs, cents:	Cable	6.90
	Demand	6.91
Lire, cents:	Demand	4.60
Marks, cents		2.00

Eastern Metal Market

New York, August 18.

All the markets are under the influence of seasonal activity and there is 'little doing' in any of them.

Conditions in the copper market are unchanged and prices are generally firm to steady.

The tin market is without life in any department.

Lead is the strongest of the markets with the price tendency higher and supplies still inadequate.

The zinc market shows more activity than in recent weeks, but it is not marked. Prices are higher.

Antimony is unchanged in any respect.

IRON AND STEEL

In the pig-iron market sellers appear to be sold well ahead and are accepting new business with caution. Consumers have been rushing to fill nearby deliveries as fully as possible and as a result some sellers are reported to be asking fancy prices. The market has reached the point where makers are no longer anxious and examine all orders carefully. Some predict that prices will continue high for some time.

There is an active demand for sheets which is centring on galvanized products just at present. There is a good demand for large sizes of black sheets.

In general the market is quiet with most producers active. Railroad conditions are improving and shipments on contracts are progressing with more speed. August is always a dull month and no developments of interest are transpiring.

COPPER

While business is reported to be light, sentiment is considerably improved. The leading producers have done a moderate business during the past week, but it cannot be said that buying is even normal. They maintain prices at 19c., New York, for both Lake and electrolytic copper for delivery to November 1. The better feeling is explained as being due to a depletion of stocks in the hands of speculators. There is talk of an advance in quotations by some interests despite the inactive market, in order to meet the increased costs, inevitable as a result of freight-rate advances. For the first time in more than a month bids by buyers appeared on the New York Metal Exchange; this was a surprise. They offered 18.25c. spot, August and September, and 18.50c. for October, but sellers held firmly at 19c. and 19.25c., respectively. Foreign demand is not as active as previously, due to lower values for exchange and to political conditions in Europe. Copper output in August is not expected to show any improvement over July.

TIN

Conditions in this market are pronounced by traders as duller than in many months, even more so than many can recall. The leading consumers are still out of the market and this has been a feature for some weeks. Even dealers and speculators are taking no interest. The market may be characterized as dull and steady with prices for spot Straits tin largely nominal at around 48c., New York, which was the quotation yesterday. Import prices are around 48 to 48.25c. There is an absence of any transactions on the New York Metal Exchange, none having been reported last week against only 25 tons the week before. There have been some offerings of Chinese tin at 43.50 to 44c., New York, which has tended to interfere with demand for better grades. An unusual occurrence has been the non-arrival of any tin for some days or almost a week. The receipts this far this month have been about 3000 tons with 5545 tons still afloat. The London market was steady yesterday with spot Straits quoted at £285 per ton and spot standard at £274 10s. with futures at £281 15s.

LEAD

The leading interest advanced its price on August 12 another ¼c., bringing it to 8.25c., St. Louis, or 9c., New York. The outside market had been up to this level for some weeks so the change was not a surprise and was regarded as entirely warranted. While demand is not heavy and is still largely confined to early-delivery metal, the fact that supplies are meagre constitutes an element of strength. In the outside market spot and early-delivery lead has sold as high as 9.12½ to 9.25c., New York. Nothing is obtainable at 9c., New York, except from the American Smelting & Refining Co., providing it has it to spare. The first purchases of English lead are now arriving here, 400 tons having been received a few days ago.

ZINC

A much better sentiment prevails and prices are advancing. There has been more interest from consumers but the market cannot be said to be active. Prime Western for early delivery is quoted at 8.05c., St. Louis, or 8.40c., New York, at which level sales have been made. There have also been sales made for September at 8.10c., St. Louis, and for October at 8.15c., St. Louis. There is considerable uncertainty as to far-forward delivery prices, due to the effect of freight-rates on costs, etc. There is some talk of an advance in prices soon because of this. There are reports of a distinct shortage of stocks which by some is pointed to as a decided influence. It is stated that the supply has fallen to a point where producers have become buyers to cover delivery obligations.

ANTIMONY

The market continues dull with no change in prices which are 7.25c. per lb., New York, duty paid, for wholesale lots for early delivery. Jobbing lots are ¼c. higher.

ALUMINUM

Virgin metal, 98 to 99% pure, continues obtainable at 33c. per lb., New York, from the leading interest, with 31.50 to 32.50c. per lb., asked by other sellers. These apply to wholesale lots for early delivery.

ORES

Tungsten: The market continues inactive with prices unchanged around \$5 to \$5.50 per unit and up. There has been a little business but it is regarded as difficult to do any because prices are too low or under the cost of production. Bolivian ore is about \$6 to \$6.50 per unit.

Molybdenum: Conditions are unchanged with the market quiet and prices nominal at around 65 to 75c. per lb. of MoS₂ in regular 90% concentrate.

Manganese: There is almost no business and prices are nominal at 70c. per unit for high-grade ore.

Manganese-Iron Alloys: The summer dullness has permeated this market. Inquiry for ferro-manganese is limited to moderate quantities for early delivery, for which around \$200 per ton, delivered, is the price. The spiegeleisen market is strong, some sellers asking \$82.50 furnace and others \$85.

A market letter from London says: "The movement of prices for silver has been upward. India is not much in evidence as a buyer. There have been some purchases for China, where, despite the lack of export business, great demand for the metal for speculative purposes in India, has created a market. The strength does not lie so much in the moderate demand as in the fact that the United States is unable or unwilling to feed it. Some silver from America has been sold here, and some has come from the Continent."

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A NOVEL DREDGE-LIGHT

The accompanying illustration shows a make-shift apparatus devised by the Dredging Department of the Bethlehem Shipbuilding Corporation for lighting the bow and stern of its gold-dredges. It consists of an old automobile head-light mounted on a hinge with a $\frac{1}{2}$ -in. bolt bent in the form of a quadrant, with notches filed in the quadrant so that it

A Novel Dredge-Light

can be centred at any angle and held there. The light is pivoted in a horizontal direction and held with an ordinary clamping-bolt. The whole arrangement is mounted on a piece of $2\frac{1}{2}$ -in. pipe and is used in repair work on the bank, or at the stern of the dredge. It is easy to adjust this light so as to throw the rays exactly where wanted.

The picture of the man in front is that of an old dredge operator, but due to his modesty his name is withheld.

BIG TRUCKS CAUSE LESS ROAD-WEAR

There is probably no more vital nor widely discussed topic of interest in the motor-truck industry just now than the relation of heavy-truck duty to road-wear. Much opinion has been expressed to the effect that large-capacity vehicles, by virtue of their greater weight, are in some measure responsible for excessive road deterioration. Some interesting

facts in this connection were brought out recently in an interview with R. E. Fulton, vice-president of the International Motor Co., manufacturers of Mack trucks. "No one realizes better than the motor-truck manufacturers", said Mr. Fulton, "the necessity of putting into force legislation which will preserve the roads and enable this country to approach more rapidly its ultimate state of highway perfection. It is doubtful, however, whether the policy which is now pursued of restricting large-capacity trucks will be effective in accomplishing this end. There are but two possible ways of preserving the roads through legislation: either the total tonnage of traffic passing over the roads must be reduced or the road-wear per ton of material transported must be decreased. Barring the heavy-duty truck is an attempt to save the roads by the first method. The elimination of this most economical of motor transportation units tends to make the cost of highway transportation prohibitive. If eliminating the $7\frac{1}{2}$ -ton truck would divert the freight formerly carried in those units to some entirely different transportation agency then its elimination would reduce road-wear. The other carriers are not able to cope with the traffic already in their own legitimate sphere. Therefore, if this freight is to be moved at all it must go over the highways in a larger number of light vehicles regardless of the increased cost of such transportation.

"Apparently the object of prohibiting the $7\frac{1}{2}$ -ton truck is to decrease total tonnage over the highways. Let us see how it works out. The average truck of one-ton capacity weighs by itself approximately two tons. On the other hand, in a $7\frac{1}{2}$ -ton truck there is less than one ton of vehicle weight for each ton of freight capacity. This means that in transporting seven tons of material in one-ton trucks, 21 tons of traffic (total weight of vehicle and cargo) will pass over the roads, whereas if transported in a $7\frac{1}{2}$ -ton truck the road will have to bear only 14 tons of traffic. In other words, the tonnage formerly shipped in $7\frac{1}{2}$ -ton trucks would have to be decreased 33% before there would be any actual reduction in the volume of traffic. Furthermore, to even approach the economy of the heavy-duty truck in bulk-hauling, the light vehicle must resort to excessive road speeds, which have been definitely proved to be more destructive than increased weight.

"Although it might be advisable at the present time to decrease the tonnage transported over highways, it is not possible to do so because there is no other agent capable of taking over this traffic. Thus the only alternative is to direct legislation toward reducing the road-wear per ton of materials transported. The results of tests recently conducted by the Bureau of Public Roads at Washington indicate clearly the way in which this can be done. These tests show that the road impact is the principal cause of highway destruction, and also that the road impact does not necessarily increase in direct proportion to the size of the truck, but is governed by the amount of weight which a truck carries below its springs. For instance a $5\frac{1}{2}$ -ton chain-driven truck fully loaded delivered only 68% of the road impact pressure produced by a 3-ton shaft-driven truck operated under the same conditions. This is accounted for by the

fact that a chain-driven truck carries all of its driving mechanism on the frame above the springs, whereas in a shaft-driven truck the entire weight of the final drive and its housing rides directly on the rear axle and the blow which this delivers to the road is unrelieved by springs.

"Not gross weight but actual pressure on the road is the all-important thing to be considered in framing laws to protect the highways."

MULTIPLE-CYLINDER AMMONIA-COMPRESSOR

Marked innovations in design, resulting in exceptional simplicity and reliability, are claimed for the Norwalk refrigerating plant, a product which has recently been added to the line of the Norwalk Iron Works Co., South Norwalk, Connecticut. The Norwalk company has during the past 40 years built up a world-wide demand for its air and gas-compressors, and its reputation for quality products is fully sustained in this new product.

The plant is of the multiple-cylinder ammonia-compressor type. It is furnished with motor or gas-engine drive, and is thus equally suited to city or country use. The fundamental design is standardized, so that while the cylinders and operating parts are adapted to the various capacities, the principle of construction remains unchanged throughout the whole line. This policy, the Norwalk engineers point out, has resulted in a degree of efficiency which would not otherwise have been possible.

The internal mechanism of the Norwalk plant is free from bolts and nuts, a big factor in avoiding derangements. There is nothing to work loose and call for adjustments or replacements. The operating parts are few and rugged. The drive is by eccentric shaft, and a feature typical of Norwalk simplicity is the floating ring-bearing used between the eccentric ring and the ring on the connecting-rod. This ring-bearing turns constantly under the action of the connecting-rod ring, and, being of softer metal than the rings between which it functions, it takes all wear. The major parts of the mechanism are thus protected for long life, while the ring-bearing can be replaced when necessary at trifling cost.

This policy of having the mechanism automatically safeguard itself is applied at all points, resulting not only in uninterrupted efficiency and economy but also in exceptionally long life for the whole plant. Another departure which has had a great deal to do with the success of this plant is the use of graphite semi-fluid lubrication, instead of oil. One of the problems in mechanical lubrication, especially in the smaller types of machines, has been due to the oil volatilizing and passing out into the refrigerating system. This not only meant poor lubrication but at the same time seriously interfered with the refrigerating process. Norwalk lubrication is declared to be trouble-proof.

AN AMERICAN-MADE GOLD-DREDGE FOR NEW ZEALAND

An example of the far-reaching activities of American industry is to be found in a gold-dredge that has been designed and constructed in New York for the purpose of operating in New Zealand goldfields. This dredge is being built by the New York Engineering Co. and is similar to the dredge constructed for operations in Alaska. The hull is 115 ft. 6 in. overall; beam, 50 ft.; depth, 11 ft.; and is built of native pine. Power for dredging, pumping, and shifting position is furnished by Westinghouse electric motors, while twelve men, four men to a shift, constitute the crew.

The general method of dredging is as follows: The digging-ladder carrying the buckets is lowered and dirt is scooped up. This dirt is dropped on the conveyor-belt and is carried to the screen. Here it is screened and washed and the refuse is dropped from the screen to another conveyor-

belt, where it is carried to the stacker and deposited. The pay-dirt that remains is further washed on gold-tables and then passed to a gold-box where the gold is recovered. The remaining deposit in this gold-box is treated about once a week with mercury so that most of the gold is obtained either in nuggets or in the form of an amalgam.

A winch motor is used to change the position of the dredge. On frequent occasions the dredge is shifted to shoal water, and the pumps must then be operated before it can be re-floated.

The digging-ladder carrying the buckets is 100 ft. long and weighs 110,000 lb. There are 73 buckets, each bucket, empty, weighing 3000 lb., with a load-capacity of about 10.5 cwt. When in operation, 18 buckets per minute are dug, and a linear speed of 54 ft. per minute is obtained from a 200-hp. slip-ring motor with a magnetic controller for reversing and 50% speed-reduction.

The screen is 40 ft. long with diameter of 7 ft. and weighs approximately 6500 lb. A 50-hp. slip-ring motor operates this screen at seven revolutions per minute. About 8000 gallons of water is used per minute in washing and the three pumps (high-pressure, low-pressure, and nozzle-pumps) are driven by Westinghouse squirrel-cage motors of 125, 60, and 25 hp., respectively.

The conveyor-belt for transportation of dirt from the screen to the stacker is 42 in. wide and 130 ft. long, and the stacker is operated by a 40-hp. slip-ring motor. Winch-drive is furnished by a 25-hp. slip-ring motor and a 10-kw. transformer is used for lighting purposes. All motors are of the three-phase, 60-cycle, 2200-volt, alternating-current type, and have special impregnated windings to protect them from moisture. Complete protection is afforded the motor by overload and no-voltage release; a time element attachment is furnished which permits a fixed overload for a definite time before releasing.

Power is furnished by a hydro-electric plant and feeders are run along the ground to the dredge. As alternating current is used, the dredge can be operated a considerable distance from the plant. Dredges of this type have operated on a cost basis of 6½¢ per cubic yard and in one instance where records were available, 418,745 cu. yd. has been dug in a period of two years.

COMMERCIAL PARAGRAPHS

Rickard & Sloan, Inc., purveyors of 'Productive Publicity' have moved their offices from the Evening Post building to 25 Spruce street, New York, where they will have more ample quarters for their growing business.

On September 1, 1920, the **Flexible Steel Lacing Co.** will occupy its new factory at 4607-4631 Lexington street, Chicago. The company's entire facilities will be devoted to the manufacture of Alligator steel belt-lacing, high-duty belt fasteners, Turtle belt-fasteners, Flexco lamp-guards, and Flexco-lok lamp-guards.

The **Oxweld Acetylene Co.**, the world's largest manufacturer of oxy-acetylene welding and cutting apparatus, has established Pacific Coast sales and distributing headquarters at San Francisco, with offices at 1077 Mission street. Additional sales representatives' office are maintained at the following points: Los Angeles, 646 Maple avenue; Salt Lake City, 908 Kearns Bldg.; Portland, 90 First street; Seattle, 433 Pioneer Bldg. Leo Romney, with headquarters at San Francisco, is Pacific sales manager. The territory embraces the States of Washington, Oregon, Idaho, Utah, Arizona, California, Nevada, and the counties of Lincoln, Sweetwater, and Uintah in Wyoming. This territory was formerly served from Chicago and Los Angeles. Removal of headquarters to San Francisco was made necessary to secure a more central location for supplying the company's rapidly growing business in the Pacific States where Oxweld apparatus is extensively used in the metal industries and shipyards.

The Samson
Crusher

The McCool
Pulverizer

A Complete Massco Laboratory Outfit

This MASSCO Laboratory Outfit ought to be a part of every mining laboratory, every milling plant; it certifies conclusions regarding the proper treatment method for any ore and serves to help regulate and adjust the process after your mill is in operation.

THE SAMSON CRUSHER—does the heavy work in your laboratory flotation mill—it's the primary breaker.

THE McCOOL PULVERIZER—prepares the pulp quickly, uniformly, and to the desired mesh—ideal for laboratory grinding.

THE LABORATORY WILFLEY—a completely equipped concentrating table with two decks, roughing and finishing, each 14x30 inches, standard enclosed head motion, improved rocker bearings and all the Wilfley features.

THE RUTH FLOTATION MACHINE—duplicating large-scale mill conditions—a most efficient flotation, aeration, emulsification, and immediate froth discharge.

THE HEUSSER BALANCE—accurate and rapid weighings are easily accomplished with a Heusser Balance. There are some very special features you should know about.

MASSCO CLAY GOODS—Muffles, Crucibles, Roasting Dishes and Scorifiers of superior service—their uniform excellence will please you.

Laboratory tests cost but a fractional percentage of the amount involved in building a mill—and laboratory work with the MASSCO Outfit furnishes reliable milling data—you can depend on it.

T. A. RICKARD, . . . Editor

NAMES of the 'investors' in Mr. Ponzi's get-rich-quick scheme have been published by the Boston 'Post'. We can imagine what a rush there must have been on the part of Mr. Rice and other 'fiscal agents', especially those engaged in the art of incubating oily wild-cats, to get hold of this list of 'suckers'. To them it will be a mine, more real than those in which they invite 'investors' to put their money.

LAST week several Republican newspapers came out with a flaring head-line stating that the British embassy at Washington had contributed \$87,500 to the Democratic campaign fund. This was corrected next day in small print. Now Mr. Myron Herrick says that "western European statesmen are hoping for a return of the Republican party to power". This, of course, is featured in the Democratic press. Thus one bit of silliness balances another. Meanwhile a more serious statement is made that "British interests take a hand in California senatorial fight". It appears that a local publication, 'The British-Californian', objects to one candidate as a "dangerous demagogue". Forthwith, there is foolish talk of "sinister foreign influence". Undoubtedly a paper avowedly conducted in behalf of British residents in California has no business to take sides in the senatorial election. Indeed, it is most undesirable that any publication should be published on non-American lines and for the purpose of promoting solidarity among foreigners.

SOME of these 'literary gents' have queer ideas about mines. For example, in the current 'Atlantic Monthly' we read this: "Authors are like miners: they put the precious metal into their books; but when one gets to the mine, there is apt to be a lot of 'slag' about!" The exclamation mark is well placed. The simile is mixed. Apparently the idea is that as authors put precious things into their books, so miners put precious metal into their mines, that is, they 'salt' them; but when you read the book you find a good deal of piffle scattered over the pages, and when you go to the mines you find heaps of slag. The comparison might hold, if miners made slag at the mine; they don't; the slag is made at the smelter, which usually is far from the mine. For 'slag', read 'rock'. Part of the slag in the 'Atlantic' quotation is to be found in the word "apt", which is out of place. The word means 'suitable' or 'appropriate'; it is not a correct synonym for 'likely'. However, it is fair to add, the

article that contained the above-quoted slag also contained several bits of crystalline gold.
